## Abstract

Let $\Gamma \subset \mathbb{Q}^{*}$ be a finitely generated subgroup and let $p$ be a prime number such that the reduction group $\Gamma_{p}$ is a well defined subgroup of the multiplicative group $\mathbb{F}_{p}^{*}$. Firstly, given that $\Gamma \subseteq \mathbb{Q}^{*}$, assuming the Generalized Riemann Hypothesis, we determine an asymptotic formula for the average over prime numbers, powers of the order of the reduction group modulo $p$. The problem was previously considered by Pomerance and Kulberg for the rank 1 case. When $\Gamma$ contains only positive numbers, we are also able to give an explicit expression for the involved density in terms of an Euler product. The first part is concluded with some numerical computations. In the second part, for any $m \in \mathbb{N}$ we prove an asymptotic formula for the average of the number of primes $p \leq x$ for which the index $\left[\mathbb{F}_{p}^{*}: \Gamma_{p}\right]=m$. The average is performed over all finitely generated subgroups $\Gamma=\left\langle a_{1}, \ldots, a_{r}\right\rangle \subset \mathbb{Q}^{*}$, with $a_{i} \in \mathbb{Z}$ and $a_{i} \leq T_{i}$ with a range of uniformity: $T_{i}>\exp \left(4(\log x \log \log x)^{\frac{1}{2}}\right)$ for every $i=1, \ldots, r$. We also prove an asymptotic formula for the mean square of the error terms in the asymptotic formula with a similar range of uniformity. The case of rank 1 and $m=1$ corresponds to the classical Artin conjecture for primitive roots and has already been considered by Stephens in 1969.

## Acknowledgements

I wish to express my gratitude to my advisor Prof. Francesco Pappalardi for his enlightening advices and his constant encouragement. I would also like to thank Prof. Luigi Chierchia, and my colleagues Giulio Meleleo, Stefano Guarino, Flavio Lombardi, Antonio Cigliola, Lorenzo Menici, Fabio Felici for their warm welcome to the department, I always felt like home in the department during the years I lived in Rome.

A special thanks goes to my mother, my grandfather and my whole family members for their love and support. I would like to express my appreciation to my beloved friends Remzi Ay, Betül Perçinel and Necdet Perçinel and Ayhan Dil, their support was priceless. I also would like to thank my sincere friend Ümit Işlak for his help during my career and his proofreading of my thesis.

In addition, I would like express my thanks to my M.Sc. advisor Asst. Prof. Özlem Beyarslan and my B.Sc. advisor Prof. Alövsat Müslümov for their support and encouragement. Also, I would like to thank to all my friends in Turkey, for their confidence and support during my career. Last but not least, many thanks to the Nesin Mathematics Village, where I had wonderful experiences with amazing people.

## Notations and Terminology

- $\mathbb{Z}$ - The ring of integers
- $\mathbb{N}-\{1,2, \ldots\}$
- $\mathbb{Z} / p \mathbb{Z}$ - The ring of integers modulo prime number $p$
- $\mathbb{F}_{p}^{*}$ - Multiplicative group of the field of $p$ elements
- $\langle a\rangle$ - Subgroup of $\mathbb{F}_{p}^{*}$ generated by $a$
- $\operatorname{gcd}(a, b)$ - Greatest common divisor of the integers $a, b \in \mathbb{Z}$
- $\operatorname{lcm}[a, b]$ - Least common multiple of the integers $a, b \in \mathbb{Z}$
- $\ell_{p}(a)$ - Order of an element $a \in \mathbb{F}_{p}^{*}$
- $\omega(n)$ - Number of distinct prime factors of $n$
- $\delta(\eta)$ - The field discriminant of $\mathbb{Q}(\sqrt{\eta})$
- $\varphi(n)$ - Euler totient function
- $\mu(n)$ - Möbius function
- $\operatorname{rad}(n)$ - Product of distinct prime numbers dividing $n$
- $p, q, \ell$ - Denotes prime numbers
- $\prod_{p}, \prod_{q}, \Pi_{\ell}$ - Denotes the product taken over prime numbers
- $J_{t}(k)$ - Jordan's totient function: $k^{t} \prod_{p \mid k}\left(1-\frac{1}{p^{t}}\right)$
- $f(x)=O(g(x))$ or $f(x) \ll g(x)$ - There exists a positive real number $C$ and a real number $x_{0}$ such that $|f(x)| \leq C|g(x)|$ for all $x>x_{0}$
- $f(x) \sim g(x)-\lim _{x \rightarrow \infty} \frac{f(x)}{g(x)}=1$
- $f(x)<_{\lambda} g(x)$ - Denotes that the implied constant depends on a given parameter $\lambda$
- $f(x)=o(g(x))-\lim _{x \rightarrow \infty} \frac{f(x)}{g(x)}=0$
- $\pi(x)$ - Denotes the number of primes up to a number $x$
- $\operatorname{Li}(x)-\int_{2}^{x} \frac{d t}{\log t}$

## Chapter 1

## Introduction

In his classic work Disquisitones Arithmeticae, Carl F. Gauss questioned why the rational number $\frac{1}{7}$ has a period of length 6 , whereas $\frac{1}{11}$ has a period of length 2 . In the same work, he observed that for any prime number $p \neq 2,5, \frac{1}{p}$ has the same period with the order of $10 \bmod p$, and that the period of $\frac{1}{p}$ is long when 10 is a primitive root modulo $p$, where an integer $a$ is said to be a primitive root modulo $p$ if $\langle a(\bmod p)\rangle=\mathbb{F}_{p}^{*}$. With this observation, Gauss further questioned whether 10 would be a primitive root for infinitely many prime numbers.

Later on, in 1927, Artin conjectured that any non-zero integer $a \neq \pm 1$, which is not a perfect square, is a primitive root for infinitely many primes. Letting $p$ be a prime number, and denoting the multiplicative order of an integer $a$ modulo $p$ by $\ell_{a}(p)$, we say that the integer $a$ is primitive root modulo $p$ if $\ell_{a}(p)=p-1$. Also defining $N_{a}(x)$ as the number of primes up to $x$ for which $\ell_{a}(p)=p-1$, we may formulate Artin's initial conjecture as:

Conjecture 1.1. Let $a$ be a fixed integer such that $a \neq \pm 1,0$ or a perfect square. Write $a=b^{h}$ where $b \in \mathbb{Z}$ is not a perfect power and $h \in \mathbb{N}$. Then,

$$
N_{a}(x) \sim A_{h} \frac{x}{\log x}
$$

as $x \rightarrow \infty$ where

$$
A_{h}=\prod_{\substack{q \mid h \\ q \text { prime }}}\left(1-\frac{1}{q-1}\right) \prod_{\substack{q \nmid h \\ q \text { prime }}}\left(1-\frac{1}{q(q-1)}\right) .
$$

Let us now briefly discuss Artin's heuristic argument towards the conjecture. First note that $a$ is primitive root modulo $p$ if and only if $a^{\frac{p-1}{q}} \not \equiv 1$ modulo $p$ for all prime divisor $q$ of $p-1$. Equivalently, $a$ is a primitive root $\bmod p$ if and only if the following two conditions are not satisfied simultaneously

$$
\begin{gather*}
p \equiv 1 \quad \bmod q  \tag{1.1}\\
a^{\frac{p-1}{q}} \not \equiv 1 \quad \bmod p . \tag{1.2}
\end{gather*}
$$

Fixing a prime $q$, by Dirichlet's Theorem, the number of primes $p$, that satisfies the first condition has frequency

$$
\frac{1}{q-1}
$$

Also, the number of primes $p$ that satisfy the second condition (except integers $a$ that are $q$-th powers) has frequency $\frac{1}{q}$. Now, assuming that the two conditions in (1.1) and (1.2) are independent, one would expect that the probability of these two events occurring simultaneously is $\frac{1}{q(q-1)}$. Since we would like to have neither of these occur for any prime $q$, the natural guess for the probability that $a$ is primitive root $(\bmod p)$ then would be

$$
\prod_{q}\left(1-\frac{1}{q(q-1)}\right)
$$

which is known as the Artin constant.
In 1957, Derrick H. Lehmer discovered some deviations from the constant suggested by Artin, and after some correspondence between Artin and Lehmer (see [26]), Artin added a correction factor to his initial conjecture. In 1967, Hooley [9] proved that Artin's conjecture is true and that we may obtain an asymptotic formula for $N_{a}(x)$, under the additional assumption that GRH (Generalized Riemann Hypothesis) holds.

Theorem 1.2. [9] Suppose $a \in \mathbb{Z} \backslash\{ \pm 1,0\}$ which is not a perfect square. If the GRH holds for
the Dedekind zeta functions for the fields $\mathbb{Q}\left(\zeta_{k}, a^{1 / k}\right)$ with $k \in \mathbb{N}$ square-free, and where $\zeta_{k}$ is a primitive $k$-th root of unity, then

$$
N_{a}(x)=A(a) \pi(x)+O\left(\frac{x \log \log x}{(\log x)^{2}}\right)
$$

where $A(a)$ is a constant depending on $a$.
Several generalizations of Artin's conjecture have been studied by various authors during the subsequent years (for an exhaustive survey see [16]).

Until so far, the best unconditional result about Artin's conjecture is due to Heath-Brown [8], Gupta and Murty [6]: One of 2,3 , or 5 is a primitive root modulo $p$ for infinitely many primes $p$.

Next, we focus on results on average multiplicative order of an integer $a$. In 2005, V. I. Arnold [1] conjectured that on average $\ell_{a}(n) \sim c(a) \frac{n}{\log n}$, where $c(a)$ is a positive constant depending on $a$. His heuristic argument was based on the physical principle of turbulence, and it was noted by Arnold that his reasoning was supported by billions of numerical experiments. Given co-prime integers $a$, $n$ with $n>0$ and $|a|>0$, if we define the average multiplicative order of $a$ by

$$
T_{a}(x):=\frac{1}{x} \sum_{\substack{n \leq x \\(a, n)=1}} \ell_{a}(n),
$$

then the conjecture of Arnold can be stated as: If $|a|>1$ then

$$
T_{a}(x) \sim c(a) \frac{x}{\log x},
$$

for some constant $c(a)$.
However, in 2007, Shparlinski [23] showed under the GRH, if $|a|>1$,

$$
T_{a}(x) \gg \frac{x}{\log x} \exp \left(c(a)(\log \log \log x)^{\frac{3}{2}}\right),
$$

for some constant $c(a)>0$.

In 2012, Pomerance and Kulberg [10], sharpened Shparlinski's result to

$$
T_{a}(x)=\frac{x}{\log x} \exp \left(\frac{B \log \log x}{\log \log \log x}(1+o(1))\right)
$$

as $x \rightarrow \infty$, uniformly in $a$ with $1<|a| \leq \log x$. The upper bound implicit in this result holds unconditionally.

Our main interest in this thesis will be on average results over prime numbers. In this direction, in 1976, Stephens [25] proved that, again under the GRH assumption, if $a$ is an integer which is not a perfect $h$ power for any $h \geq 2$, then

$$
\sum_{p \leq x} \frac{\ell_{a}(p)}{p-1}=c_{a} \cdot \frac{x}{\log x}+O\left(\frac{x \log \log x}{\log ^{2} x}\right),
$$

where $c_{a}$ is a constant depend on $a$.
As another related result, Pomerance and Kulberg prove the following theorem in their aforementioned paper [10].

Theorem 1.3. [10] Assume the GRH holds. Then for any given rational $a \neq 0, \pm 1$

$$
\frac{1}{\pi(x)} \sum_{p \leq x} \ell_{a}(p)=\frac{1}{2} c_{a} \cdot x+O\left(\frac{x}{(\log x)^{2-4 / \log \log \log x}}\right),
$$

where

$$
c_{a}:=\sum_{k=1}^{\infty} \frac{\varphi(k) \operatorname{rad}(k)(-1)^{\omega(k)}}{k^{2}\left[\mathbb{Q}\left(\zeta_{k}, a^{1 / k}\right): \mathbb{Q}\right]},
$$

and the series $c_{a}$ converges absolutely.
Indeed, it is known that $c_{a}$ is a rational multiple of $c=\prod_{p}\left(1-\frac{p}{p^{3}-1}\right)$, which is again a result of Pomerance and Kulberg. To formulate this rigorously, we first need some further notation. Write $a= \pm\left(a_{0}\right)^{h}$ where $h$ is a positive integer and $a_{0}>0$ is not an exact power of a rational number, and write $a_{0}=a_{1} a_{2}$ where $a_{1}$ is a square-free integer and $a_{2}$ is a rational number. Let $n=\operatorname{lcm}\left[2 e+1 ; \delta\left(a_{1}\right)\right]$, for $a>0$ and $e$ be the 2-adic valuation $v_{2}(h)$. Also consider the multiplicative
function $f(k)=(-1)^{\omega(k)} \operatorname{rad}(k)(h, k) / k^{3}$, which for prime powers reduces to

$$
f\left(p^{j}\right)=-p^{1-3 j+\min \left(j, v_{p}(h)\right)} .
$$

Then, defining

$$
F(p, t):=\sum_{j=0}^{t-1} f\left(p^{j}\right), \quad F(p):=\sum_{j=0}^{\infty} f\left(p^{j}\right),
$$

the precise expression obtained for $c_{a}, a>0$, obtained by Pomerance and Kulberg in [10] is the following representation

$$
\begin{equation*}
c_{a}=c \prod_{p \mid h} \frac{F(p)}{1-\frac{p}{p^{3}-1}}\left(1+\prod_{p \mid n} \frac{F(p)-F\left(p, v_{p}(n)\right)}{F(p)}\right) . \tag{1.3}
\end{equation*}
$$

In Chapter 2, we generalize the result of Pomerance and Kulberg (see Theorem 1.3) to any finitely generated subgroup $\Gamma \subset \mathbb{Q}^{*}$ of $\mathbb{Q}^{*}$. This result is also submitted for publication [21].

Before stating our result rigorously, we need some other definitions. Let $\Gamma \subseteq \mathbb{Q}^{*}$ be a finitely generated multiplicative subgroup. The support of $\Gamma$ is the (finite) set of prime numbers $p$ for which the $p$-adic valuation $v_{p}(g) \neq 0$ for some $g \in \Gamma$. We denote this set by Supp $\Gamma$ and define $\sigma_{\Gamma}=\prod_{p \in \operatorname{Supp} \Gamma} p$. For each prime number $p \nmid \sigma_{\Gamma}$, the reduction of $\Gamma$ modulo $p$ is well defined. That is,

$$
\Gamma_{p}=\{g \quad(\bmod p): g \in \Gamma\} .
$$

If $\Gamma=\left\langle a_{1}, a_{2}, \ldots, a_{r}\right\rangle$ then we denote by $\Gamma^{\frac{1}{k}}$ the group generated by

$$
\left\langle a_{1}^{\frac{1}{k}}, a_{2}^{\frac{1}{k}}, \ldots, a_{r}^{\frac{1}{k}}\right\rangle
$$

The following theorem is one of our main results in this thesis, and its proof will be included in Chapter 2.

Theorem 1.4. Let $\Gamma \subseteq \mathbb{Q}^{*}$ be a finitely generated multiplicative subgroup with rank $r \geq 2$ and
assume that the Generalized Riemann Hypothesis holds for $\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right), k \in \mathbb{N}$. Let

$$
\begin{equation*}
C_{\Gamma, t}:=\sum_{k \geq 1} \frac{J_{t}(k)(\operatorname{rad}(k))^{t}(-1)^{\omega(k)}}{k^{2 t}\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]} \tag{1.4}
\end{equation*}
$$

Then the series $C_{\Gamma, t}$ converges absolutely, and as $x \rightarrow \infty$

$$
\begin{equation*}
\sum_{p \leq x}\left|\Gamma_{p}\right|^{t}=\operatorname{li}\left(x^{t+1}\right)\left(C_{\Gamma, t}+O_{\Gamma}\left(\frac{\log \log x}{(\log x)^{r}}\right)\right) \tag{1.5}
\end{equation*}
$$

where the constant implied by the $O_{\Gamma}$-symbol may depend on $\Gamma$.
Moreover, again in Chapter 2, we give an explicit expression for the involved density in terms of an Euler product when $\Gamma$ contains only positive numbers.

Let us next move to a discussion of Artin's conjecture without the GRH assumption for which we still do not have satisfactory results. Just one year after the work of Hooley, in 1968, Goldfeld [5] showed unconditionally that for each $D>1$

$$
\begin{equation*}
N_{a}(x)=A \operatorname{li} x+O\left(\frac{x}{(\log x)^{D}}\right) \tag{1.6}
\end{equation*}
$$

holds for all integers $a \leq N$ with at most $c_{1} N^{\frac{9}{10}}(5 \log x+1)^{h+D+2}$ exceptions where $h=\frac{x}{\log N}, A$ is Artin's constant, $c_{1}$ and constant of O-term are positive and depend on only $D$.

Later in 1969, Stephens [24] not only showed that in average the asymptotic formula 1.6 holds, but also making use of the normal order method of Turan, he proved that the number of exceptions is bounded by $O(N)$ when

$$
N>\exp \left(6(\log x \log \log x)^{\frac{1}{2}}\right)
$$

and as $N, x$ tends to infinity. The following theorems are again due to Stephens and they were used to prove his results just mentioned.

Theorem 1.5. [24] If

$$
N>\exp \left(4(\log x \log \log x)^{\frac{1}{2}}\right)
$$

then

$$
\frac{1}{N} \sum_{a \leq N} N_{a}(x)=A \operatorname{li} x+O\left(\frac{x}{(\log x)^{D}}\right),
$$

where $A$ is Artin's constant, and the constant $D>1$ is arbitrary.

Theorem 1.6. [24] Let $A$ be Artin's constant, and $E>2$ be an arbitrary real number. Then, for

$$
N>\exp \left(6(\log x \log \log x)^{\frac{1}{2}}\right),
$$

we have

$$
\frac{1}{N} \sum_{a \leq N}\left(N_{a}(x)-A \operatorname{li} x\right)^{2} \ll \frac{x^{2}}{(\log x)^{E}}
$$

For any integer $|a|>1$ which is not a perfect square, Artin's conjecture is about the number of primes which satisfy the relation $\left[F_{p}^{*}:\langle a(\bmod p)\rangle\right]=1$. We can define a new counting function to enumerate the prime numbers which $a$ generates a group of index $m \in \mathbb{N}$ in $F_{p}^{*}$,

$$
\begin{equation*}
N_{a}(x, m)=\#\left\{p \leq x: p \nmid a,\left[F_{p}^{*}:\langle a \quad \bmod p\rangle\right]=m\right\} . \tag{1.7}
\end{equation*}
$$

The following theorem was proven by Moree.

Theorem 1.7. [17] Let $m$ be an arbitrary positive integer. Then for $T>\exp \left(4(\log x \log \log x)^{1 / 2}\right)$, we have

$$
\begin{equation*}
\frac{1}{T} \sum_{a \leq T} N_{a, m}(x)=\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} \frac{\varphi((p-1) / m)}{p-1}+O\left(\frac{x}{(\log x)^{E}}\right) \tag{1.8}
\end{equation*}
$$

for any constant $E>2$.
In Chapter 3, we generalize the result of Moree given in Theorem 1.7 and the results of Stephens given in Theorems 1.5 and 1.6 to the $r$-rank case, which is part of a joint work with Lorenzo Menici [14]. Also, we prove an asymptotic formula for the average of the number of primes $p \leq x$ for which the index $\left[\mathbb{F}_{p}^{*}: \Gamma_{p}\right]=m$. The average is performed over all finitely generated subgroups $\Gamma=$
$\left\langle a_{1}, \ldots, a_{r}\right\rangle \subset \mathbb{Q}^{*}$, with $a_{i} \in \mathbb{Z}$ and $a_{i} \leq T_{i}$ with a range of uniformity: $T_{i}>\exp \left(4(\log x \log \log x)^{\frac{1}{2}}\right)$ for every $i=1, \ldots, r$. The main result of Chapter 3 is summarized in the following theorem.

Theorem 1.8. Assume $T^{*}:=\min \left\{T_{i}: i=1, \ldots, r\right\}>\exp \left(4(\log x \log \log x)^{\frac{1}{2}}\right)$ and $m \leq(\log x)^{D}$ for an arbitrary positive constant $D$. Then

$$
\frac{1}{T_{1} \cdots T_{r}} \sum_{\substack{a_{i} \in \mathbb{Z} \\ 0<a_{1} \leq T_{1}}} N_{\left\langle a_{1}, \cdots, a_{r}\right\rangle, m}(x)=C_{r, m} \operatorname{Li}(x)+O\left(\frac{x}{(\log x)^{M}}\right),
$$

where $C_{r, m}=\sum_{n \geq 1} \frac{\mu(n)}{(n m)^{r} \varphi(n m)}$ and $M>1$ is arbitrarily large.
Furthermore, if $T^{*}>\exp \left(6(\log x \log \log x)^{\frac{1}{2}}\right)$, then

$$
\frac{1}{T_{1} \cdots T_{r}} \sum_{\substack{a_{i} \in \mathbb{Z} \\ 0<a_{1} \leq T_{1}}}\left\{N_{\left\langle a_{1}, \cdots, a_{r}\right\rangle, m}(x)-C_{r, m} \operatorname{Li}(x)\right\}^{2} \ll \frac{x^{2}}{(\log x)^{M^{\prime}}},
$$

where $M^{\prime}>2$ is arbitrarily large.

## Chapter 2

## Average Multiplicative Order of $\Gamma$

## Over Primes

### 2.1 Preliminary Definitions and Results

We denote by $\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right)$ the extension of the cyclotomic field $\mathbb{Q}\left(\zeta_{k}\right)$ obtained by adding the $k$-th roots of all the elements in $\Gamma . \mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right)$ is a finite Galois extension of $\mathbb{Q}$ and it is well known that

$$
\operatorname{Gal}\left(\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right) / Q\left(\zeta_{k}\right)\right) \cong \Gamma\left(\mathbb{Q}\left(\zeta_{k}\right)^{*}\right) / \mathbb{Q}\left(\zeta_{k}\right)^{*} .
$$

For details on the Theory of Kummer's extensions see [12, Theorem 8.1]. If $\eta \in \mathbb{Q}^{*}$, by $\delta(\eta)$ we denote the field discriminant of $\mathbb{Q}(\sqrt{\eta})$. So, if $\eta \in \mathbb{Z}$ is square-free, $\delta(\eta)=\eta$ if $\eta=1 \bmod$ (4) and $\delta(\eta)=4 \eta$ otherwise. For any $k \in \mathbb{N}^{+}$,

$$
\Gamma(k)=\Gamma \cdot \mathbb{Q}^{* k} / \mathbb{Q}^{* k} .
$$

For any square-free integer $\eta$, let

$$
t_{\eta}= \begin{cases}\infty & \text { if for all } t \geq 0, \eta^{2^{t}} \mathbb{Q}^{* 2^{t^{t+1}}} \notin \Gamma\left(2^{t+1}\right)  \tag{2.1}\\ \min \left\{t \in \mathbb{N}: \eta^{2^{t}} \mathbb{Q}^{* 2^{t+1}} \in \Gamma\left(2^{t+1}\right)\right\} & \text { otherwise. }\end{cases}
$$

We define the index of subgroup $\operatorname{ind}\left(\Gamma_{p}\right)=\frac{p-1}{\mid \Gamma_{p}}$. Let $\Gamma$ be a finitely generated subgroup of $\mathbb{Q}^{*}$ of rank $r$ and let $\left(a_{1}, \ldots, a_{r}\right)$ be a $\mathbb{Z}$-basis of $\Gamma$. We write $\operatorname{Supp}(\Gamma)=\left\{p_{1}, \ldots, p_{s}\right\}$. Then we can construct the $s \times r$-matrix with coefficients in $\mathbb{Z}$ :

$$
M\left(a_{1}, \ldots, a_{r}\right)=A=\left(\begin{array}{ccc}
\alpha_{1,1} & \ldots & \alpha_{1, r} \\
\vdots & & \vdots \\
\alpha_{s, 1} & \ldots & \alpha_{s, r}
\end{array}\right)
$$

 $r$. For all $i=1, \ldots, r$ we define the $i-$ th exponent of $\Gamma$ by

$$
\Delta_{i}=\Delta_{i}(\Gamma)=\operatorname{gcd}\left(\operatorname{det} A: A \text { is an } i \times i \text { minor of } M\left(a_{1}, \ldots, a_{r}\right)\right)
$$

For $m \in \mathbb{N}$, we have (see [3, Proposition 2] )

$$
|\Gamma(m)|=\frac{\varepsilon_{m, \Gamma} \times m^{r}}{g c d\left(m^{r}, m^{r-1} \Delta_{1}, \ldots, m \Delta_{r-1}, \Delta_{r}\right)}
$$

where

$$
\varepsilon_{m, \Gamma}= \begin{cases}1 & \text { if } m \text { is odd or if }-1 \notin \Gamma\left(\mathbb{Q}^{*}\right)^{m}  \tag{2.2}\\ 2 & \text { if } m \text { is even and if }-1 \in \Gamma\left(\mathbb{Q}^{*}\right)^{m}\end{cases}
$$

Then, for every prime power $p^{\alpha}$, we have (see [8])

$$
\begin{equation*}
\left|\Gamma\left(p^{\alpha}\right)\right|=p^{\max \left\{0, \alpha-v_{p}\left(\Delta_{1}\right), \ldots,(r-1) \alpha-v_{p}\left(\Delta_{r-1}\right), r \alpha-v_{p}\left(\Delta_{r}\right)\right\}} \tag{2.3}
\end{equation*}
$$

Proposition 2.1. Let $g \in \mathbb{Q}^{+} \backslash\{1\}$ and we write $g=\left(g_{0}\right)^{h}$ where $h$ is a positive integer and $g_{0}$ is
not a perfect power and let $g_{0}=g_{1} g_{2}^{2}$ where $g_{1}$ is square free, then we have $t_{g_{1}}=v_{2}(h)$ and $t_{\eta}=\infty$ if $\eta \neq g_{1}$.

Proof. Let $m=v_{2}(h)$ then,

$$
\left|\Gamma\left(2^{t+1}\right)\right|=2^{t+1-\min (t+1, m)}
$$

The condition $\eta^{2^{t}} \mathbb{Q}^{* 2^{t+1}} \in \Gamma\left(2^{t+1}\right)$ is satisfied if the group $\Gamma\left(2^{t+1}\right)$ has an element of order 2 . It could happen if $t \geq m$, and in this case, the only element in $\Gamma\left(2^{t+1}\right)$ of order 2 is $\left(g_{1}\right)^{2^{t}} \mathbb{Q}^{* 2^{t+1}}$. So, $t_{g_{1}}=m=v_{2}(h)$ and $t_{\eta}=\infty$ for all other values of $\eta$. Note that $t_{\eta}$ is defined if $\eta$ is square-free.

The following statement is obtained using the effective version of the Chebotarev Density Theorem due to Serre (see [22, Theorem 4]).

Lemma 2.2 (Chebotarev Density Theorem). Let $\Gamma \subset \mathbb{Q}^{*}$ be a finitely generated subgroup of rank $r$ and $k \in \mathbb{N}^{+}$. The GRH for the Dedekind zeta function of $\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right)$ implies that

$$
\begin{equation*}
\#\left\{p \leq x: p \notin \operatorname{Supp} \Gamma, k \mid \operatorname{ind}\left(\Gamma_{p}\right)\right\}=\frac{\operatorname{li}(x)}{\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]}+O\left(\sqrt{x} \log \left(x k^{r+1} \sigma_{\Gamma}\right)\right) \tag{2.4}
\end{equation*}
$$

The following Lemma describes explicitly the degree of $\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]$ (see $[19$, Lemma 1 and Corollary 1]).

Lemma 2.3. Let $k \geq 1$ be an integer. With the notation above, we have

$$
\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\left(\zeta_{k}\right)\right]=|\Gamma(k)| /|\widetilde{\Gamma}(k)|,
$$

where

$$
\widetilde{\Gamma}(k)=\left(\Gamma \cap \mathbb{Q}\left(\zeta_{k}\right)^{2^{v_{2}(k)}}\right) \cdot \mathbb{Q}^{* 2^{v_{2}(k)}} / \mathbb{Q}^{* 2^{v_{2}(k)}}
$$

Furthermore, in the special case when $\Gamma \subset \mathbb{Q}^{+}$,

$$
\widetilde{\Gamma}(k)=\left\{\eta\left|\sigma_{\Gamma}, \eta^{2^{v_{2}(k)-1}} \mathbb{Q}^{* 2^{v_{2}(k)}} \in \Gamma\left(2^{v_{2}(k)}\right), \delta(\eta)\right| k\right\} .
$$

The next results follows from Lemma 2.2, see also [19, Equation 7].

Corollary 2.4. Let $\Gamma \subset \mathbb{Q}^{*}$ be a subgroup with $r=\operatorname{rank}_{\mathbb{Z}}(\Gamma)$ and let $k \in \mathbb{N}$. Then

$$
\begin{equation*}
2 k^{r} \geq\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\left(\zeta_{k}\right)\right] \geq \frac{(k / 2)^{r}}{\Delta_{r}(\Gamma)} . \tag{2.5}
\end{equation*}
$$

Next Lemma is implicit in the work of C. R. Matthews (see [13]).

Lemma 2.5. Assume that $\Gamma \subseteq \mathbb{Q}^{*}$ is a multiplicative subgroup of rank $r \geq 2$ and assume that $\left(a_{1}, \ldots, a_{r}\right)$ is a $\mathbb{Z}$-basis of $\Gamma$. Let $t \in \mathbb{R}, t>1$. We have the following estimate

$$
\begin{equation*}
\#\left\{p \notin \operatorname{Supp} \Gamma:\left|\Gamma_{p}\right| \leq t\right\}<_{\Gamma} \frac{t^{1+1 / r}}{\log t} . \tag{2.6}
\end{equation*}
$$

Theorem 2.6. Assume the GRH. Let $\Gamma$ be a multiplicative subgroup of $\mathbb{Q}^{*}$ of rank $r \geq 2$. Then, for $1 \leq L \leq \log x$, we have

$$
\begin{equation*}
\#\left\{p \leq x: p \notin \operatorname{Supp} \Gamma,\left|\Gamma_{p}\right| \leq \frac{p-1}{L}\right\} \ll_{\Gamma} \frac{\pi(x)}{L^{r}} . \tag{2.7}
\end{equation*}
$$

The proof of the above is routine and easier than the main theorem in [9] and the one in $[1$, Theorem 6]. Hence, we will skip some of the details.

Proof. Let $t, L \leq t \leq x$, be a parameter that will be chosen later.

- first step: First consider primes $p \notin \operatorname{Supp} \Gamma$ such that $\left|\Gamma_{p}\right| \leq \frac{p-1}{t}$. By Lemma 2.5, we have

$$
\begin{equation*}
\#\left\{p \notin \operatorname{Supp} \Gamma:\left|\Gamma_{p}\right| \leq \frac{x}{t}\right\}<_{\Gamma} \frac{(x / t)^{1+1 / r}}{\log (x / t)} \tag{2.8}
\end{equation*}
$$

- second step: Next consider the primes $p \notin \operatorname{Supp} \Gamma$ such that there exists a prime $q, L \leq q \leq t$ such that $q \left\lvert\, \operatorname{ind}\left(\Gamma_{p}\right)=\frac{p-1}{\left|\Gamma_{p}\right|}\right.$. If we apply Lemma 2.2, we obtain

$$
\begin{align*}
\#\left\{p \leq x: p \notin \operatorname{Supp} \Gamma, q \mid \operatorname{ind}\left(\Gamma_{p}\right)\right\} & =\frac{\operatorname{li}(x)}{\left[\mathbb{Q}\left(\zeta_{q}, \Gamma^{1 / q}\right): \mathbb{Q}\right]}+O_{\Gamma}(\sqrt{x} \log (x q)) \\
& \ll \Gamma \frac{\pi(x)}{q^{r} \varphi(q)}+\sqrt{x} \log (x q) \tag{2.9}
\end{align*}
$$

where in the latter estimate we have applied Corollary 2.4. If we sum the above over primes $q: L \leq q \leq t$, we obtain

$$
\begin{align*}
\#\left\{p \leq x: p \notin \operatorname{Supp} \Gamma, \exists q \mid \operatorname{ind}\left(\Gamma_{p}\right), L \leq q \leq t\right\} & \leq \sum_{\substack{q \text { prime } \\
L \leq q \leq t}}\left(\frac{\pi(x)}{q^{r} \varphi(q)}+\sqrt{x} \log (x q)\right) \\
& \ll \frac{\pi(x)}{L^{r}}+x^{1 / 2} t \log x . \tag{2.10}
\end{align*}
$$

- third step: The primes $p$ that were not counted in previous steps, have the property that all the prime divisors of $\operatorname{ind}\left(\Gamma_{p}\right)$ belong to the interval $[1, L]$. Hence, for such primes $p, \operatorname{ind}\left(\Gamma_{p}\right)$ is divisible for some integer $d$ in $\left[L, L^{2}\right]$.

Applying again Lemma 2.2 and Corollary 2.4, and taking the sum over $d$ we deduce that the total number of such primes is

$$
\begin{equation*}
<_{\Gamma} \sum_{\substack{d \in \mathbb{N} \\ L<d \leq L^{2}}}\left(\frac{\pi(x)}{d^{r} \varphi(d)}+x^{\frac{1}{2}} \log (x d)\right) \lll \frac{\pi(x)}{L^{r}}+x^{1 / 2} L^{2} \log x \tag{2.11}
\end{equation*}
$$

A choice of $t=\frac{x^{1 / 2}}{L^{r} \log ^{2} x}$ allows us to conclude the proof.
The Theorem of Wirsing [28] is formulated as follows.

Lemma 2.7. Assume that a real valued multiplicative function $h(n)$ satisfies the following conditions.

- $h(n) \geq 0, n=1,2, . . ;$
- $h\left(p^{n}\right) \leq c_{1} c_{2}{ }^{v}, v=2,3 \ldots$, for some constants $c_{1}, c_{2}$ with $c_{2}<2$;
- there exists a constant $\tau>0$ such that

$$
\begin{equation*}
\sum_{p \leq x} h(p)=(\tau+o(1)) \frac{x}{\log x} . \tag{2.12}
\end{equation*}
$$

Then for any $x \geq 0$,

$$
\begin{equation*}
\sum_{n \leq x} h(n)=\left(\frac{1}{e^{\gamma \tau} \Gamma(\tau)}+o(1)\right) \frac{x}{\log x} \prod_{p \leq x} \sum_{\nu \geq 0} \frac{h\left(p^{\nu}\right)}{p^{\nu}} \tag{2.13}
\end{equation*}
$$

where $\gamma$ is the Euler constant, and

$$
\begin{equation*}
\Gamma(s)=\int_{0}^{\infty} e^{-t} t^{s-1} d t \tag{2.14}
\end{equation*}
$$

is the gamma function.

### 2.2 Proof of Theorem 1.4

The proof use the methods of Kurlberg and Pomerance [1, Theorem 2].

Proof of Theorem 1.4. Let $z=\log x$. We have

$$
\sum_{p \leq x}\left|\Gamma_{p}\right|^{t}=\sum_{\substack{p \leq x \\ \operatorname{ind}\left(\bar{\Gamma}_{p}\right) \leq z}}\left|\Gamma_{p}\right|^{t}+\sum_{\substack{p \leq x \\ \operatorname{ind}\left(\bar{\Gamma}_{p}\right)>z}}\left|\Gamma_{p}\right|^{t}=A+E .
$$

We write $\left|\Gamma_{p}\right|^{t}=\frac{(p-1)^{t}}{\operatorname{ind}^{t}\left(\Gamma_{p}\right)}$ and use the identity $\frac{1}{\operatorname{ind}^{t}\left(\Gamma_{p}\right)}=\sum_{u v \mid \operatorname{ind}\left(\Gamma_{p}\right)} \frac{\mu(v)}{u^{t}}$, after splitting the sum we have

$$
\begin{aligned}
A & =\sum_{\substack{p \leq x \\
\operatorname{ind}\left(\Gamma_{p}\right) \leq z}}(p-1)^{t} \sum_{u v \mid \operatorname{ind}\left(\Gamma_{p}\right)} \frac{\mu(v)}{u^{t}} \\
& =\sum_{p \leq x}(p-1)^{t} \sum_{\substack{u v \mid \operatorname{ind}\left(\Gamma_{p}\right) \\
u v \leq z}} \frac{\mu(v)}{u^{t}}-\sum_{\substack{p \leq x \\
\operatorname{ind}\left(\Gamma_{p}\right)>z}}(p-1)^{t} \sum_{\substack{u v \mid \operatorname{ind}\left(\Gamma_{p}\right) \\
u v \leq z}} \frac{\mu(v)}{u^{t}} \\
& =A_{1}-E_{1} .
\end{aligned}
$$

The main term $A_{1}$ is

$$
A_{1}=\sum_{u v \leq z} \frac{\mu(v)}{u^{t}} \sum_{\substack{u v \mid \operatorname{ind}_{p \leq x}\left(\Gamma_{p}\right)}}(p-1)^{t}
$$

Applying partial summation and using Lemma 2.2 on GRH, we can write the inner some as

$$
\frac{\operatorname{li}\left(x^{t+1}\right)}{\left[\mathbb{Q}\left(\zeta_{u v}, \Gamma^{1 / u v}\right): \mathbb{Q}\right]}+O\left(x^{t+\frac{1}{2}} \log x\right) .
$$

Then it follows,

$$
A_{1}=\operatorname{li}\left(x^{t+1}\right) \sum_{u v \leq z} \frac{\mu(v)}{u^{t}\left[\mathbb{Q}\left(\zeta_{u v}, \Gamma^{1 / u v}\right): \mathbb{Q}\right]}+O\left(x^{t+\frac{1}{2}} \log x \sum_{n \leq z}\left|\sum_{u v=n} \frac{\mu(v)}{u^{t}}\right|\right)
$$

The inner sum in the $O$-term is bounded by $\frac{\varphi(n)}{n}$ so that the $O$-term above is $O\left(x^{t+\frac{1}{2}} \log ^{2}(x)\right)$.

Next we use the elementary fact $J_{t}(\operatorname{rad}(k))=J_{t}(k)\left(\frac{\operatorname{rad}(k)}{k}\right)^{t}$ and $\sum_{v \mid k} \mu(v) v^{t}=\prod_{p \mid k}\left(1-p^{t}\right)=$ $(-1)^{\omega(k)} J_{t}(\operatorname{rad}(k))=(-1)^{\omega(k)} \frac{J_{t}(k)(\operatorname{rad}(k))^{t}}{k^{t}}$. So

$$
\sum_{u v=k} \frac{\mu(v)}{u^{t}\left[\mathbb{Q}\left(\zeta_{u v}, \Gamma^{1 / u v}\right): \mathbb{Q}\right]}=\sum_{v \mid k} \frac{\mu(v) v^{t}}{k^{t}\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]}=\frac{(-1)^{\omega(k)} J_{t}(k)(\operatorname{rad}(k))^{t}}{\left.k^{2 t}\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]\right)}
$$

Let $C_{\Gamma, t}:=\sum_{k \geq 1} \frac{J_{t}(k)(\operatorname{rad}(k))^{t}(-1)^{\omega(k)}}{k^{2 t}\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]}$, then we have

$$
\sum_{u v \leq z} \frac{\mu(v)}{u^{t}\left[\mathbb{Q}\left(\zeta_{u v}, \Gamma^{1 / u v}\right): \mathbb{Q}\right]}=C_{\Gamma, t}-\sum_{k>z} \frac{J_{t}(k)(\operatorname{rad}(k))^{t}(-1)^{\omega(k)}}{k^{2 t}\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]}
$$

Since $\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]=\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\left(\zeta_{k}\right)\right] \varphi(k)$, if we use Corollary 2.4, we have

$$
\frac{J_{t}(k)(\operatorname{rad}(k))^{t}(-1)^{\omega(k)}}{k^{2 t}\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]} \ll \frac{(\operatorname{rad}(k))^{t}}{k^{t+1} k^{r}} .
$$

Finally, we have

$$
A_{1}=\operatorname{li}\left(x^{t+1}\right)\left(C_{\Gamma, t}+O\left(\frac{1}{z^{r}}\right)\right)
$$

It remains to estimate the error terms $E$ and $E_{1}$. Applying Theorem 2.6:

$$
E \ll \frac{x^{t}}{z^{t}} \frac{\pi(x)}{z^{r}}
$$

In order to estimate $E_{1}$, we calculate

$$
\left|\sum_{\substack{u v \mid n \\ u v \leq z}} \frac{\mu(v)}{u^{t}}\right| \leq \sum_{u \mid n} \frac{1}{u^{t}} \sum_{\substack{v \mid n \\ v \leq z}} 1 \leq \frac{\tau(n) \sigma_{t}(n)}{n^{t}}
$$

so

$$
E_{1} \leq \sum_{z<n} \frac{\tau(n) \sigma_{t}(n)}{n^{t}} \sum_{\substack{p \leq x \\ n \mid \operatorname{ind}\left(\Gamma_{p}\right)}}(p-1)^{t} .
$$

Then applying Lemma 2.2 and Corollary 2.4 we obtain that

$$
E_{1} \ll x^{t} \pi(x) \sum_{z<n} \frac{\tau(n) \sigma_{t}(n)}{n^{t} \varphi(n) n^{r}} .
$$

Let $g(n):=\frac{\tau(n) \sigma_{t}(n)}{n^{t-1} \varphi(n)}, \sum_{p \leq x} g(p)=(2+o(1)) \frac{x}{\log x}$. Using Lemma 2.7(in our case $\tau$ is 2 ), we have

$$
\sum_{n \leq x} g(n)=\left(\frac{1}{e^{\gamma^{2}}}+o(1)\right) \frac{x}{\log x} \prod_{p \leq x}\left(1+\frac{p}{(p-1)\left(p^{t}-1\right)} \sum_{\nu \geq 1} \frac{(\nu+1)\left(p^{\nu t+t}-1\right)}{p^{\nu t+\nu}}\right)
$$

To make the product convergent we add a correction factor, and invoke Merten's third formula, we have

$$
\sum_{n \leq x} g(n) \sim x \log x
$$

Let $G(n):=\sum_{n \leq x} g(n)$ using partial summation, we have

$$
\sum_{z<n} \frac{g(n)}{n^{r+1}}=\lim _{T \rightarrow \infty}\left(\frac{G(T)}{T^{r+1}}-\frac{G(z)}{z^{r+1}}\right)-\int_{z}^{\infty} G(u) \frac{d}{d u}\left(\frac{1}{u^{r+1}}\right) \ll \frac{\log z}{z^{r}} .
$$

Therefore, we obtain

$$
E_{1} \ll x^{t} \pi(x) \frac{\log z}{z^{r}}
$$

We have chosen $z=\log x$, finally we have

$$
\sum_{p \leq x}\left|\Gamma_{p}\right|^{t}=\operatorname{li}\left(x^{t+1}\right) C_{\Gamma, t}+O\left(\frac{x^{t+1} \log \log x}{(\log x)^{r+1}}\right) .
$$

### 2.3 Density Calculations

Further on, for the case $t=1$ we use $C_{\Gamma}$ instead of $C_{\Gamma, 1}$. Kulberg and Pomerance in [1] consider the case when $\Gamma=\langle g\rangle$ has rank 1 . In the special case when $\Gamma \subset \mathbb{Q}^{+}$, we express the value of $C_{\Gamma}$ as an Euler product.

Theorem 2.8. Assume that $\Gamma$ is a finitely generated subgroup of $\mathbb{Q}^{+}$. Then,

$$
\begin{align*}
C_{\Gamma, t} & =\prod_{p}\left(1-\sum_{\alpha \geq 1} \frac{p^{t}-1}{p^{\alpha(t+1)-1}\left|\Gamma\left(p^{\alpha}\right)\right|(p-1)}\right) \\
& \times\left(1+\sum_{\substack{\eta \mid \sigma_{\Gamma} \\
\eta \neq 1}} S_{\eta} \prod_{p \mid 2 \eta}\left(1-\left(\sum_{\alpha \geq 1} \frac{p^{t}-1}{p^{\alpha(t+1)-1}\left|\Gamma\left(p^{\alpha}\right)\right|(p-1)}\right)^{-1}\right)^{-1}\right) \tag{2.15}
\end{align*}
$$

where

$$
\begin{equation*}
S_{\eta}=\frac{\sum_{\alpha \geq \gamma_{\eta}} \frac{2^{t}-1}{2^{\alpha(t+1)-1}\left|\Gamma\left(2^{\alpha}\right)\right|}}{\sum_{\alpha \geq 1} \frac{2^{t}-1}{2^{\alpha(t+1)-1}\left|\Gamma\left(2^{\alpha}\right)\right|}} \tag{2.16}
\end{equation*}
$$

and $\gamma_{\eta}=\max \left\{1+t_{\eta}, v_{2}(\delta(\eta))\right\}$.

Proof of Theorem 2.8. We start by splitting the sum $C_{\Gamma, t}$ as

$$
\begin{equation*}
C_{\Gamma, t}:=\sum_{k \geq 1} \frac{J_{t}(k)(\operatorname{rad}(k))^{t}(-1)^{\omega(k)}}{k^{2 t}\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]}=A_{1}+A_{2} . \tag{2.17}
\end{equation*}
$$

where $A_{1}$ is the sum of the terms corresponding to odd values of $k$ and $A_{2}$ is the sum of the terms corresponding to even values of $k$. Note that if $\Gamma \subseteq \mathbb{Q}^{+}$by Lemma 2.3, we have

$$
\begin{equation*}
\left[\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right): \mathbb{Q}\right]=\frac{\varphi(k)|\Gamma(k)|}{|\widetilde{\Gamma}(k)|} \tag{2.18}
\end{equation*}
$$

and if $k$ is even,

$$
\begin{equation*}
\widetilde{\Gamma}(k)=\left\{\eta\left|\sigma_{\Gamma}, \eta^{2^{v_{2}(k)-1}} \mathbb{Q}^{* 2^{v_{2}(k)}} \in \Gamma\left(2^{v_{2}(k)}\right), \delta(\eta)\right| k\right\} \tag{2.19}
\end{equation*}
$$

while if $k$ is odd $\widetilde{\Gamma}(k)=\{1\}$. We define

$$
f_{t}(k)=\frac{J_{t}(k)(\operatorname{rad}(k))^{t}(-1)^{\omega(k)}}{k^{2 t} \varphi(k)|\Gamma(k)|} .
$$

Note that if $D \in \mathbb{N}^{+}$is even, since $f_{t}(k)$ is multiplicative in $k$, then

$$
\begin{equation*}
\sum_{\substack{k \geq 1 \\ \operatorname{gcd}(k, D)=1}} f_{t}(k)=\prod_{p \nmid D}\left(1+\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right)=\prod_{p \nmid D}\left(1-\sum_{\alpha \geq 1} \frac{p^{t}-1}{p^{\alpha(t+1)-1}\left|\Gamma\left(p^{\alpha}\right)\right|(p-1)}\right) . \tag{2.20}
\end{equation*}
$$

Therefore, we have the identity

$$
\begin{equation*}
A_{1}:=\prod_{p>2}\left(1+\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right)=\prod_{p>2}\left(1-\sum_{\alpha \geq 1} \frac{p^{t}-1}{p^{\alpha(t+1)-1}\left|\Gamma\left(p^{\alpha}\right)\right|(p-1)}\right) . \tag{2.21}
\end{equation*}
$$

We can write $A_{2}$ as,

$$
\begin{align*}
A_{2} & =\sum_{\eta \mid \sigma_{\Gamma}} \sum_{\substack{k \geq 1,2 \mid k \\
\Gamma}} \frac{J_{t}(k)(\operatorname{rad}(k))^{t}(-1)^{\omega(k)}}{k^{2 t} \varphi(k)|\Gamma(k)|} \\
& =\sum_{\eta \mid \sigma_{\Gamma}} \sum_{\substack{\alpha \geq 1 \\
\eta^{2^{\alpha-1}} \mathbb{Q}^{* 2^{\alpha}} \in \Gamma\left(2^{\alpha}\right)}} \sum_{\substack{k \geq 1 \\
v \\
v_{2}(k)=\alpha \\
\delta(\eta) \mid k}} f_{t}(k) \\
& =\sum_{\eta \mid \sigma_{\Gamma}} \sum_{\substack{\alpha \geq 1 \\
\eta^{2 \alpha-1} \\
\alpha \geq v_{2}(\delta(\eta))}} \frac{-\left(2^{t}-1\right)}{2^{\alpha(t+1)-1}\left|\Gamma\left(2^{\alpha}\right)\right|} \sum_{\substack{k \geq 1 \\
2 \nmid k \\
\delta(\eta) \mid 8 k}} f_{t}(k) . \tag{2.22}
\end{align*}
$$

Now write $\delta(\eta)=2^{v_{2}(\delta(\eta))} M$. Then

$$
\begin{align*}
\sum_{\substack{k \geq 1 \\
2 \nmid k \\
\delta(\eta) \mid 8 k}} f_{t}(k) & =\prod_{\substack{p>2 \\
p \nmid M}}\left(1+\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right) \prod_{\substack{p>2 \\
p \mid M}}\left(\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right) \\
& =A_{\substack{p>2 \\
p \mid M}}\left(\left(1+\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right)^{-1}\left(\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right)\right) . \tag{2.23}
\end{align*}
$$

Hence, if $t_{\eta}$ is the quantity defined in (2.1), then

$$
C_{\Gamma, t}:=A_{1} \times\left(1+\sum_{\substack { \eta \mid \sigma_{\Gamma} \\
\begin{subarray}{c}{\alpha \geq 1 \\
\alpha \geq v_{2}(\delta(\eta)){ \eta | \sigma _ { \Gamma } \\
\begin{subarray} { c } { \alpha \geq 1 \\
\alpha \geq v _ { 2 } ( \delta ( \eta ) ) } }\end{subarray}} \frac{-\left(2^{t}-1\right)}{2^{\alpha(t+1)-1}\left|\Gamma\left(2^{\alpha}\right)\right|} \prod_{\substack{p>2 \\
p \mid M}}\left(1+\left(\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right)^{-1}\right)^{-1}\right)
$$

Now let

$$
\delta_{\Gamma}:=\prod_{p \text { prime }}\left(1+\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right)=\prod_{p \text { prime }}\left(1-\sum_{\alpha \geq 1} \frac{p^{t}-1}{p^{\alpha(t+1)-1}\left|\Gamma\left(p^{\alpha}\right)\right|(p-1)}\right)
$$

and deduce that

$$
C_{\Gamma, t}=\delta_{\Gamma}\left(1+\sum_{\substack{\eta \mid \sigma_{\Gamma} \\ \eta \neq 1}} \frac{\sum_{\alpha \geq \gamma_{\eta}} \frac{2^{t}-1}{\sum_{\alpha \geq 1}^{\alpha(t+1)-1}\left|\Gamma\left(2^{\alpha}\right)\right|}}{\sum_{2^{\alpha(t+1)-1}\left|\Gamma\left(2^{\alpha}\right)\right|}^{2^{t}-1}} \prod_{p \mid 2 \eta}\left(1+\left(\sum_{\alpha \geq 1} f_{t}\left(p^{\alpha}\right)\right)^{-1}\right)^{-1}\right)
$$

where $\gamma_{\eta}=\max \left\{1+t_{\eta}, v_{2}(\delta(\eta))\right\}$ and this completes the proof.

In the special case when $\Gamma$ consists of prime numbers and $t=1$, the above formula can be considerably simplified:

Corollary 2.9. Let $\Gamma=\left\langle p_{1}, \ldots, p_{r}\right\rangle$ where all the $p_{i}$ 's are prime numbers and $r \geq 1$, with the notation above, we have

$$
\begin{align*}
C_{\left\langle p_{1}, \ldots . p_{r}\right\rangle} & =\prod_{p}\left(1-\frac{p}{p^{r+2}-1}\right) \\
& \times\left(1+\sum_{\substack{\eta \mid p_{1} \cdots p_{r} \\
\eta \neq 1}} \frac{1}{2^{\max \left\{0, v_{2}(\delta(\eta) / 2)\right\}(r+2)}} \prod_{\ell \mid 2 \eta} \frac{\ell}{\ell+1-\ell^{r+2}}\right) . \tag{2.24}
\end{align*}
$$

The quantity

$$
\begin{equation*}
C_{r}=\prod_{p}\left(1-\frac{p}{p^{r+2}-1}\right) \tag{2.25}
\end{equation*}
$$

can be computed with arbitrary precision:

| $r$ | $C_{r}$ |
| :---: | :---: |
| 1 | $0.57595996889294543964316337549249669251 \cdots$ |
| 2 | $0.82357659279814332395380438513901050177 \cdots$ |
| 3 | $0.92190332088740008067545348360869076931 \cdots$ |
| 4 | $0.96388805107176946676374437726734997946 \cdots$ |
| 5 | $0.98282912014687261524345691713313004185 \cdots$ |
| 6 | $0.99168916383630008819101294319807859837 \cdots$ |
| 7 | $0.99593155027181927318700546733612700362 \cdots$ |
| 8 | $0.99799372275691129752727433560285572887 \cdots$ |
| 9 | $0.99900593591154969071253065973483263501 \cdots$ |
| 10 | $0.99950593624928276115384423618416539651 \cdots$ |

Table 2.1: Approximated values of some of the $C_{r}$ 's.

Proof of Corollary 2.9. Let $\Gamma$ be generated by prime numbers $p_{1}, \ldots, p_{r}$, since $\Delta_{i}$ 's are 1 we have $|\Gamma(k)|=k^{r}$ and $t_{\eta}=0$ for all $\eta \mid \sigma_{\Gamma}=p_{1} \cdots p_{r}$ and

$$
\gamma_{\eta}= \begin{cases}1 & \text { if } \eta \equiv 1 \bmod 4 \\ 2 & \text { if } \eta \equiv 3 \bmod 4 \\ 3 & \text { if } \eta \equiv 2 \bmod 4 .\end{cases}
$$

Furthermore,

$$
\sum_{\alpha \geq \gamma_{\eta}} \frac{1}{2^{2 \alpha-1}\left|\Gamma\left(2^{\alpha}\right)\right|}=\frac{1}{2^{\left(\gamma_{\eta}-1\right)(r+2)}} \sum_{\alpha \geq 1} \frac{1}{2^{2 \alpha-1}\left|\Gamma\left(2^{\alpha}\right)\right|}
$$

and since $|\Gamma(k)|=k^{r}$ for all $k \in \mathbb{N}^{+}$, we have that

$$
\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}=\frac{p}{p^{r+2}-1} .
$$

Hence, if we let

$$
C_{r}=\prod_{p}\left(1-\frac{p}{p^{r+2}-1}\right)
$$

then

$$
C_{\left\langle p_{1}, \ldots, p_{r}\right\rangle}=C_{r}\left(1+\sum_{\substack{\eta \mid p_{1} \cdots p_{r} \\ \eta \neq 1}} \frac{1}{2^{\left(\gamma_{\eta}-1\right)(r+2)}} \prod_{\ell \mid 2 \eta} \frac{\ell}{\ell+1-\ell^{r+2}}\right)
$$

and this completes the proof.

Furthermore, we have the following Corollary.

Corollary 2.10. Let $\Gamma$ be a finitely generated subgroup of $\mathbb{Q}^{+}$with rank $r$. Then $C_{\Gamma}$ is a non zero rational multiple of $C_{r}$.

Proof of Corollary 2.10. If we set $k_{p}=\max \left\{v_{p}\left(\Delta_{r} / \Delta_{r-1}\right), \cdots, v_{p}\left(\Delta_{1} / \Delta_{0}\right)\right\}$ then for $\alpha \geq k_{p}$, $\left|\Gamma\left(p^{\alpha}\right)\right|=p^{r \alpha-v_{p}\left(\Delta_{r}\right)}$. Hence

$$
\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}=\sum_{\alpha=1}^{k_{p}} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}+\frac{p^{v_{p}\left(\Delta_{r}\right)+1-(r+2) k_{p}}}{p^{r+2}-1} \in \mathbb{Q}
$$

In particular, if $p \nmid \Delta_{r}$, then $k_{p}=0$ and $\left|\Gamma\left(p^{\alpha}\right)\right|=p^{\alpha r}$ for all $\alpha \geq 0$ and

$$
\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}=\frac{p}{p^{r+2}-1}
$$

Therefore

$$
C_{\Gamma}=r_{\Gamma} \prod_{p \nmid \Delta_{r}}\left(1-\frac{p}{p^{r+2}-1}\right)
$$

where

$$
\begin{align*}
r_{\Gamma} \quad & =\prod_{p \mid \Delta_{r}}\left(1-\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}\right) \\
& \times\left(1+\sum_{\substack{\eta \mid \sigma_{\Gamma} \\
\eta \neq 1}} S_{\eta} \prod_{p \mid 2 \eta}\left(1-\left(\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}\right)^{-1}\right)^{-1}\right) \in \mathbb{Q} \tag{2.26}
\end{align*}
$$

Finally $C_{\Gamma}$ is a rational multiple of

$$
C_{r}=\prod_{p}\left(1-\frac{p}{p^{r+2}-1}\right)
$$

and this concludes the proof.
A calculation shows that, in the case when $\Gamma=\langle g\rangle$, the above expression for $C_{\langle g\rangle}$ coincides with the density $c_{g}$ of Pomerance and Kulberg (see equation 1.3). We will give the proof for $g>0$, in the following Corollary.

Corollary 2.11. Let $\Gamma=\langle g\rangle$ where $g \in \mathbb{Q}^{+} \backslash\{1\}$ and we write $g=\left(g_{0}\right)^{h}$ where $h$ is a positive integer and $g_{0}$ is not a perfect power and let $g_{0}=g_{1} g_{2}^{2}$ where $g_{1}$ is square free, we have $C_{\Gamma}=c_{g}$.

Proof. By Proposition 2.1, we have $t_{\eta}=\infty$ unless $\eta=g_{1}$, so $S_{\eta}$ is different than 0 only when $\eta=g_{1}$, then we have

$$
C_{\langle g\rangle}=\prod_{p}\left(1-\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}\right)\left(1+S_{g_{1}} \prod_{p \mid 2 g_{1}}\left(1-\left(\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}\right)^{-1}\right)^{-1}\right) .
$$

When the rank is 1 , for prime powers we have $\left|\Gamma\left(p^{\alpha}\right)\right|=p^{\max \left(0, \alpha-v_{p}\left(\Delta_{1}\right)\right)}$. Since $\Delta_{1}=h$, then

$$
\begin{aligned}
C_{\langle g\rangle}= & \prod_{p}\left(1-\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1} p^{\max \left\{0, \alpha-v_{p}(h)\right\}}}\right) \\
& \times\left(1+S_{g_{1}} \prod_{p \mid 2 g_{1}}\left(1-\left(\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}\right)^{-1}\right)^{-1}\right) \\
= & \prod_{p}\left(1-\sum_{\alpha \geq 1} \frac{1}{p^{3 \alpha-1}}\right) \prod_{p \mid h} \frac{\left(1-\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1+\max \left(0, \alpha-v_{p}(h)\right)}}\right)}{\left(1-\sum_{\alpha \geq 1} \frac{1}{p^{3 \alpha-1}}\right)} \\
& \times\left(1+S_{g_{1}} \prod_{p \mid 2 g_{1}}\left(1-\left(\sum_{\alpha \geq 1} \frac{1}{p^{2 \alpha-1}\left|\Gamma\left(p^{\alpha}\right)\right|}\right)^{-1}\right)^{-1}\right) .
\end{aligned}
$$

If we use the notation of Pomerance and Kulberg, which we defined previously in introduction and noting that $j-\min \left(j, v_{p}(h)\right)=\max \left(0, j-v_{p}(h)\right)$, we have

$$
\begin{align*}
C_{\langle g\rangle} & =c \prod_{p \mid h} \frac{F(p)}{1-\frac{p}{p^{3}-1}}\left(1+\frac{F(2)-F\left(2, \gamma_{g_{1}}\right)}{F(2)-1} \prod_{p \mid 2 g_{1}}\left(1+(F(p)-1)^{-1}\right)^{-1}\right) \\
& =c \prod_{p \mid h} \frac{F(p)}{1-\frac{p}{p^{3}-1}}\left(1+\frac{F(2)-F\left(2, \gamma_{g_{1}}\right)}{F(2)-1} \prod_{p \mid 2 g_{1}} \frac{F(p)-1}{F(p)}\right) \\
& =c \prod_{p \mid h} \frac{F(p)}{1-\frac{p}{p^{3}-1}}\left(1+\frac{F(2)-S\left(2, \gamma_{g_{1}}\right)}{F(2)} \prod_{p \mid g_{1}, p>2} \frac{F(p)-1}{F(p)}\right) \\
& =c \prod_{p \mid h} \frac{F(p)}{1-\frac{p}{p^{3}-1}}\left(1+\prod_{p \mid n} \frac{F(p)-F\left(p, v_{p}(n)\right)}{S(p)}\right) \tag{2.27}
\end{align*}
$$

where $n=\operatorname{lcm}\left[2 e+1 ; \delta\left(a_{1}\right)\right]$, to get last equality we used the equation $\gamma_{g_{1}}=\max \left(1+t_{g_{1}}, v_{2}\left(\delta\left(g_{1}\right)\right)\right)=$ $v_{2}(n)$ and the property $v_{p}(n)=1$ except for $p=2$.

### 2.4 Numerical Examples

In this section we compare some numerical data. The following table compares the value of $C_{\Gamma}$ as predicted by Corollary 2.9 with

$$
A_{\Gamma}=\frac{\sum_{p \leq 10^{10}}\left|\Gamma_{p}\right|}{\sum_{p \leq 10^{10}} p} .
$$

We consider the following cases:

- $\Gamma_{r}=\left\langle 2, \ldots, p_{r}\right\rangle$, the group generated by the first $r$ primes
- $\Gamma_{r}^{\prime}=\left\langle 3, \ldots, p_{r+1}\right\rangle$, the group generated by the first $r$ odd primes
- $\Gamma_{r}^{\prime \prime}=\left\langle 5, \ldots, p_{r}^{\prime \prime}\right\rangle$, the group generated by the first $r$ primes congruent to 1 modulo 4 .

| $r$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $A_{\Gamma_{r}}$ | 0.5723625220 | 0.8234145762 | 0.9219692467 | 0.9638944667 | 0.9828346715 | 0.9916961670 | 0.9959388895 |
| $C_{\Gamma_{r}}$ | 0.5723602190 | 0.8234094709 | 0.9219688310 | 0.9638925514 | 0.9828293379 | 0.9916891587 | 0.9959315465 |
| $A_{\Gamma_{r}^{\prime}}$ | 0.5797271743 | 0.8249081874 | 0.9220326599 | 0.9639044730 | 0.9828352799 | 0.9916947130 | 0.9959372205 |
| $C_{\Gamma_{r}^{\prime}}$ | 0.5797162295 | 0.8249060912 | 0.9220306381 | 0.9639002343 | 0.9828302996 | 0.9916892783 | 0.9959315614 |
| $A_{\Gamma_{r}^{\prime \prime}}$ | 0.5856374600 | 0.8246697078 | 0.9220170449 | 0.9639045923 | 0.9828329969 | 0.9916930151 | 0.9959357111 |
| $C_{\Gamma_{r}^{\prime \prime}}^{\prime \prime}$ | 0.5856399683 | 0.8246572843 | 0.9220082264 | 0.9638982767 | 0.9828301305 | 0.9916892643 | 0.9959315465 |

Table 2.2: Comparison of the results

Example 2.12. We will use the same example in [19]. Let

$$
\Gamma=\left\langle 3^{3} \cdot 11^{15}, 3^{3} \cdot 11^{3}, 3^{7} \cdot 13^{7}, 2^{2} \cdot 5^{2} \cdot 11 \cdot 13\right\rangle
$$

Then $\operatorname{Supp}(\Gamma)=(2,3,5,11,13)$ and the matrix associated to $\Gamma$ is

$$
\left(\begin{array}{cccc}
0 & 0 & 0 & 2 \\
3 & 3 & 7 & 0 \\
0 & 0 & 0 & 2 \\
15 & 3 & 0 & 1 \\
0 & 0 & 7 & 1
\end{array}\right)
$$

$\Delta_{4}(\Gamma)=2^{3} .3^{2} .7, \Delta_{3}(\Gamma)=2.3, \Delta_{2}(\Gamma)=\Delta_{1}(\Gamma)=1$ where for $i=1, \ldots, r, \Delta_{i}$ is the $i$ 'th exponent of
Г. Using this identity (2.3)

$$
\left|\Gamma\left(\ell^{j}\right)\right|=l^{\max \left\{0, j-v_{l}(1), 2 j-v_{l}(1), 3 j-v_{l}(2.3), 4 j-v_{l}\left(2^{3} .3^{2} .7\right)\right\}}
$$

After some calculations (see [19])

$$
t_{\eta}= \begin{cases}0 & \text { if } \eta \in\{1,33,29,143\} \\ 1 & \text { if } \eta \in\{30,110,130,4290\} \\ 2 & \text { if } \eta \in\{3,11,10,13,330,390,1430\} \\ \infty & \text { otherwise. }\end{cases}
$$

Then, we have

$$
s_{\eta}= \begin{cases}1 & \text { if } \eta \in\{1,33,29\} \\ 2 & \text { if } \eta \in\{143\} \\ 3 & \text { if } \eta \in\{3,11,10,13,30,110,130,330,390,1430,4290\} \\ \infty & \text { otherwise. }\end{cases}
$$

For specific $\Gamma$ in the example, we have the following results $A_{\Gamma}=0.838115336148, C_{\Gamma}=0.838100746276$.

## Chapter 3

## Average r-rank Artin Conjecture

### 3.1 Introduction

In the present work, we will discuss the average version of the $r$-rank Artin quasi primitive root conjecture. Let $\Gamma \subset \mathbb{Q}^{*}$ be a multiplicative subgroup of finite rank $r$. We denote by $N_{\Gamma, m}(x)$ the number of such primes with $\# \Gamma_{p}=\frac{p-1}{m}$. It was proven by Cangelmi, Pappalardi and Susa in [18], [3] and [20], assuming the GRH for $\mathbb{Q}\left(\zeta_{k}, \Gamma^{1 / k}\right), k \in \mathbb{N}$, that for any $\varepsilon>0$, if $m \leq x^{\frac{r-1}{(r+1)(4 r+2)}-\varepsilon}$,

$$
N_{\Gamma, m}(x)=\left(\delta_{\Gamma}^{m}+O\left(\frac{1}{\varphi\left(m^{r+1} \log ^{r} x\right.}\right)\right) \operatorname{Li}(x) \quad \text { as } x \rightarrow \infty,
$$

where $\delta_{\Gamma}^{m}$ is a rational multiple of

$$
C_{r}=\sum_{n \geq 1} \frac{\mu(n)}{n^{r} \varphi(n)}=\prod_{p}\left(1-\frac{1}{p^{r}(p-1)}\right) .
$$

Here we restrict ourselves to study subgroups $\Gamma=\left\langle a_{1}, \cdots, a_{r}\right\rangle$ with $a_{i} \in \mathbb{Z}$ for all $i=1, \ldots, r$. Notice that, since $\varphi(m n)=\varphi(m) \varphi(n) \operatorname{gcd}(m, n) / \varphi(\operatorname{gcd}(m, n))$

$$
C_{r, m}=\frac{1}{m^{r} \varphi(m)} \sum_{n \geq 1} \frac{\mu(n)}{n^{r} \varphi(n)} \prod_{p \mid \operatorname{gcd}(m, n)}\left(1-\frac{1}{p}\right)=\frac{1}{m^{r+1}} \prod_{p \mid m}\left(1-\frac{p}{p^{r+1}-1}\right)^{-1} C_{r}
$$

The proof of Theorem 1.8 (see equation (3.5) and Lemma 3.6) will lead to a side product to the asymptotic identity, for $T_{i}>\exp \left(4(\log x \log \log x)^{\frac{1}{2}}\right)$ for all $i=1, \ldots, r, m \leq(\log x)^{D}$ and any constant $M>2$ :

$$
\frac{1}{T_{1} \cdots T_{r}} \sum_{\substack{a_{i} \in \mathbb{Z} \\ 0<a_{1} \leq T_{1}}} N_{\left\langle a_{1}, \cdots, a_{r}\right\rangle, m}(x)=\sum_{\substack{p \leq x \\ 0 \equiv 1(\bmod m)}} \frac{J_{r}((p-1) / m)}{(p-1)^{r}}+O\left(\frac{x}{(\log x)^{M}}\right)
$$

where $J_{r}(n)=n^{r} \prod_{\ell \mid n}\left(1-1 / \ell^{r}\right)$ is the so called Jordan's totient function. This provides a natural generalization of Moree's result in [17].

### 3.2 Preliminary Definitions and Lemmas

In order to simplify the formulas, we introduce the following notations. Underlined letters stand for general $r$-tuples defined within some set, e.g. $\underline{a}=\left(a_{1}, \ldots, a_{r}\right) \in\left(\mathbb{F}_{p}^{*}\right)^{r}$ or $\underline{T}=\left(T_{1}, \ldots, T_{r}\right) \in\left(\mathbb{R}^{>0}\right)^{r}$; moreover, given two $r$-tuples, $\underline{a}$ and $\underline{n}$, their scalar product is $\underline{a} \cdot \underline{n}=a_{1} n_{1}+\cdots+a_{r} n_{r}$. The null vector is $\underline{0}=\{0, \ldots, 0\}$. Similarly, $\underline{\chi}=\left(\chi_{1}, \ldots, \chi_{r}\right)$ is a $r$-tuple of Dirichlet characters and given $\underline{a} \in \mathbb{Z}^{r}$, we denote the product $\chi(\underline{a})=\chi_{1}\left(a_{1}\right) \cdots \chi_{r}\left(a_{r}\right) \in \mathbb{C}$.

Additionally, $(q, \underline{a}):=\left(q, a_{1}, \ldots, a_{r}\right)=\operatorname{gcd}\left(q, a_{1}, \ldots, a_{r}\right) ;$ to avoid possible misinterpretations, we will write explicitly $\operatorname{gcd}\left(n_{1}, \ldots, n_{r}\right)$ instead of $(\underline{n})$.

Given any $r$-tuple $\underline{a} \in \mathbb{Z}^{r}$, we indicate with $\langle\underline{a}\rangle_{p}:=\Gamma_{p}$, where $\Gamma=\left\langle a_{1}, \ldots, a_{r}\right\rangle$, the reduction modulo $p$ of the subgroup $\langle\underline{a}\rangle=\left\langle a_{1}, \ldots, a_{r}\right\rangle \subset \mathbb{Q}$. Given a finite field $\mathbb{F}_{p}, \widehat{\mathbb{F}_{p}^{*}}$ will denote its relative dual group (or character group).

Let $\mathbb{C}$ be the set of complex numbers and $\mathbb{C}^{*}$ be the set of non-zeno complex numbers. A homomorphism from Abelian group $G$ to $\mathbb{C}^{*}$ is called a character of group $G$. A character $\chi$ is called Dirichlet character if $\chi$ is a function from $\mathbb{Z}$ to $\mathbb{C}^{*}$ which satisfies the following properties for a fixed integer $q$ :

- $\chi(n+q)=\chi(n)$ for any integer $n$
- $\chi(n) \neq 0$ if $\operatorname{gcd}(n, q)=1$ and $\chi(n)=0$ otherwise
- $\chi(n m)=\chi(n) \chi(m)$ for all integers $n$ and $m$.

Let $\chi$ be a character modulo $q$. We called $\chi$ is primitive if there is no positive integer $n<q$ such that $n \mid q$ and $\chi(m)=\chi(m(\bmod n))$ for all $m$. The proof of the following result can be found in any standard text book on analytic number theory.

Lemma 3.1. Let $\chi$ be a character modulo $q$, and $C(\chi)=\frac{1}{\varphi(q)} \sum_{b}^{\prime} \chi(b)$ where the sum is over primitive roots modulo $q$. Then we have

$$
\sum_{\chi \bmod q} C(\chi) \cdot \chi(a)= \begin{cases}1 & \text { if } a \text { is primitive root } \bmod q  \tag{3.1}\\ 0 & \text { otherwise } .\end{cases}
$$

Definition 3.2. Let $\chi$ be a character modulo $q$. Then Gauss sum defined as

$$
\tau(\chi)=\sum_{m=1}^{q} \chi(m) e\left(\frac{q}{m}\right)
$$

where $e(t)=e^{2 \pi i t}$.

Theorem 3.3. For each character $\chi$ modulo $q$, let

$$
S(\chi)=\sum_{n=M+1}^{M+N} a_{n} \chi(n)
$$

where $a_{n} \in \mathbb{C}$ and $M, N \in \mathbb{Z}$. Then, we have

$$
\sum_{q \leq K} \sum_{\bmod q}|S(\chi)|^{2} \ll\left(K^{2}+N\right) \sum_{n=M+1}^{M+N}\left|a_{n}\right|^{2} .
$$

We refer to Gallagher [4] for the proof.

Let $q>1$ be an integer and let $\underline{n} \in \mathbb{Z}^{r}$. We define the multiple Ramanujan sum as

$$
c_{q}(\underline{n}):=\sum_{\substack{\underline{a} \in(\mathbb{Z} / q \mathbb{Z})^{r} \\(q, \underline{a})=1}} e^{2 \pi i \underline{a} \cdot \underline{n} / q} .
$$

It is well known (see [7, Theorem 272]) that, given any integer $n$,

$$
\begin{equation*}
c_{q}(n)=\mu\left(\frac{q}{(q, n)}\right) \frac{\varphi(q)}{\varphi\left(\frac{q}{(q, n)}\right)} . \tag{3.2}
\end{equation*}
$$

In the following Lemma, we prove a similar equation for multiple Ramanujan sum.

Lemma 3.4. Let

$$
J_{r}(m):=m^{r} \prod_{\ell \mid m}\left(1-\frac{1}{\ell^{r}}\right)
$$

be the Jordan's totient function, then

$$
c_{q}(\underline{n})=\mu\left(\frac{q}{(q, \underline{n})}\right) \frac{J_{r}(q)}{J_{r}\left(\frac{q}{(q, \underline{n})}\right)} .
$$

Proof of Lemma 3.4. Let us start by considering the case when $q=\ell$ is prime. Then

$$
c_{\ell}(\underline{n})=\sum_{\underline{a} \in(\mathbb{Z} / \ell \mathbb{Z})^{r} \backslash\{\underline{0}\}} e^{2 \pi i \underline{a} \cdot \underline{n} / \ell}=-1+\prod_{j=1}^{r} \sum_{a_{j}=1}^{\ell} e^{2 \pi i a_{j} n_{j} / \ell}= \begin{cases}-1 & \text { if } \ell \nmid \operatorname{gcd}\left(n_{1}, \cdots, n_{r}\right), \\ \ell^{r}-1 & \text { otherwise }\end{cases}
$$

Next we consider the case when $q=\ell^{k}$ with $k \geq 2$ and $\ell$ prime. We need to show that

$$
c_{\ell^{k}}(\underline{n})= \begin{cases}0 & \text { if } \ell^{k-1} \nmid \operatorname{gcd}\left(n_{1}, \cdots, n_{r}\right), \\ -\ell^{r(k-1)} & \text { if } \ell^{k-1} \| \operatorname{gcd}\left(n_{1}, \cdots, n_{r}\right), \\ \ell^{r k}\left(1-\frac{1}{\ell^{r}}\right) & \text { if } \ell^{k} \mid \operatorname{gcd}\left(n_{1}, \cdots, n_{r}\right) .\end{cases}
$$

Then,

$$
\begin{aligned}
c_{\ell^{k}}(\underline{n}) & =\sum_{\substack{\underline{a} \in\left(\mathbb{Z} / \ell^{k} \mathbb{Z} \mathbb{Z}^{r} \\
(\ell, \underline{a})=1\right.}} e^{2 \pi i \underline{a} \cdot \underline{n} / \ell^{k}} \\
& =c_{\ell^{k}}\left(n_{1}\right) \prod_{j=2}^{r} \sum_{a_{j}=1}^{\ell^{k}} e^{2 \pi i a_{j} n_{j} / \ell^{k}}+c_{\ell^{k}}\left(n_{2}, \ldots, n_{r}\right) \sum_{j=1}^{k} \sum_{\substack{a_{1} \in \mathbb{Z} / \ell^{k} \mathbb{Z} \\
\left(a_{1}, \ell^{k}\right)=\ell^{j}}} e^{2 \pi i a_{1} n_{1} / \ell^{k}} \\
& =c_{\ell^{k}}\left(n_{1}\right) \prod_{j=2}^{r} \sum_{a_{j}=1}^{\ell^{k}} e^{2 \pi i a_{j} n_{j} / \ell^{k}}+c_{\ell^{k}}\left(n_{2}, \ldots, n_{r}\right) \sum_{j=1}^{k} c_{\ell^{k-j}}\left(n_{1}\right) .
\end{aligned}
$$

If we apply equation (3.2), we obtain

$$
\begin{aligned}
c_{\ell^{k}}\left(n_{1}, \ldots, n_{r}\right)= & \mu\left(\frac{\ell^{k}}{\left(\ell^{k}, n_{1}\right)}\right) \frac{\varphi\left(\ell^{k}\right)}{\varphi\left(\frac{\ell^{k}}{\left(\ell^{k}, n_{1}\right)}\right)} \prod_{j=2}^{r} \sum_{a_{j}=1}^{\ell^{k}} e^{2 \pi i a_{j} n_{j} / \ell^{k}} \\
& +c_{\ell^{k}}\left(n_{2}, \ldots, n_{r}\right) \sum_{j=1}^{k} \mu\left(\frac{\ell^{k-j}}{\left(\ell^{k-j}, n_{1}\right)}\right) \frac{\varphi\left(\ell^{k-j}\right)}{\varphi\left(\frac{\ell^{k-j}}{\left(\ell^{k-j}, n_{1}\right)}\right)}
\end{aligned}
$$

Now, for $k \geq 2$, let us distinguish the two cases:

1. $\ell^{k-1} \nmid \operatorname{gcd}\left(n_{1}, \ldots, n_{r}\right)$,
2. $\ell^{k-1} \mid \operatorname{gcd}\left(n_{1}, \ldots, n_{r}\right)$.

In the fist case we can assume, without loss of generality that $\ell^{k-1} \nmid n_{1}$. Hence $\mu\left(\frac{\ell^{k}}{\left(\ell^{k}, n_{1}\right)}\right)=0$ and
if $k_{1}=v_{\ell}\left(n_{1}\right)<k-1$, then

$$
\mu\left(\frac{\ell^{k-j}}{\left(\ell^{k-j}, n_{1}\right)}\right)=\mu\left(\ell^{\max \left\{0, k-k_{1}-j\right\}}\right)= \begin{cases}0 & \text { if } 1 \leq j \leq k-k_{1}-2 \\ -1 & \text { if } j=k-k_{1}-1 \\ 1 & \text { if } j \geq k-k_{1}\end{cases}
$$

Hence,

$$
\sum_{j=1}^{k} \mu\left(\frac{\ell^{k-j}}{\left(\ell^{k-j}, n_{1}\right)}\right) \frac{\varphi\left(\ell^{k-j}\right)}{\varphi\left(\frac{\ell^{k-j}}{\left(\ell^{k-j}, n_{1}\right)}\right)}=-\ell^{k_{1}}+\sum_{j=k-k_{1}}^{k} \varphi\left(\ell^{k-j}\right)=0
$$

In the second case, we go back to the definition of $c_{q}(\underline{n})$ and we have

$$
c_{\ell^{k}}(\underline{n})=\ell^{r(k-1)} c_{\ell}\left(\frac{n_{1}}{\ell^{k-1}}, \ldots, \frac{n_{r}}{\ell^{k-1}}\right)= \begin{cases}\ell^{r k}\left(1-\frac{1}{\ell^{r}}\right) & \text { if } \ell^{k} \mid \operatorname{gcd}\left(n_{1}, \ldots, n_{r}\right) \\ -\ell^{r(k-1)} & \text { if } \ell^{k-1} \| \operatorname{gcd}\left(n_{1}, \ldots, n_{r}\right)\end{cases}
$$

So, the formula holds for the case $q=\ell^{k}$.

We also claim that if $q^{\prime}, q^{\prime \prime} \in \mathbb{N}$ are such that $\operatorname{gcd}\left(q^{\prime}, q^{\prime \prime}\right)=1$, then

$$
c_{q^{\prime} q^{\prime \prime}}(\underline{n})=c_{q^{\prime}}(\underline{n}) c_{q^{\prime \prime}}(\underline{n}) .
$$

This amount in saying that the multiple Ramanujan sum is multiplicative in $q$. Indeed

$$
\sum_{\substack{\underline{a} \in\left(\mathbb{Z} / q^{\prime} \mathbb{Z}\right)^{r} \\\left(q^{\prime}, \underline{a}\right)=1}} e^{2 \pi i \underline{a} \cdot \underline{n} / q^{\prime}} \sum_{\substack{\underline{b} \in\left(\mathbb{Z} / q^{\prime \prime} \mathbb{Z}\right)^{r} \\\left(q^{\prime \prime}, \underline{b}\right)=1}} e^{2 \pi i \underline{b} \cdot \underline{n} / q^{\prime \prime}}=\sum_{\substack{\underline{a} \in\left(\mathbb{Z} / q^{\prime} \mathbb{Z}\right)^{r} \\ \underline{b} \in\left(\mathbb{Z} / q^{\prime \prime} \mathbb{Z}\right)^{r} \\ \operatorname{gcd}\left(q^{\prime}, \underline{a}\right)=1 \\ \operatorname{gcd}\left(q^{\prime \prime}, \underline{b}\right)=1}} e^{2 \pi i\left[n_{1}\left(q^{\prime \prime} a_{1}+q^{\prime} b_{1}\right)+\cdots+n_{r}\left(q^{\prime \prime} a_{r}+q^{\prime} b_{r}\right)\right] /\left(q^{\prime} q^{\prime \prime}\right)}
$$

since $\operatorname{gcd}\left(q^{\prime}, q^{\prime \prime}\right)=1$, the result follows from the following remarks:

- for all $j=1, \ldots r$, as $a_{j}$ runs through a complete set of residues modulo $q^{\prime}$ and as $b_{j}$ runs through a complete set of residues modulo $q^{\prime \prime}, q^{\prime \prime} a_{j}+q^{\prime} b_{j}$ runs through a complete set of residues modulo $q^{\prime} q^{\prime \prime}$
- for all $\underline{a} \in\left(\mathbb{Z} / q^{\prime} \mathbb{Z}\right)^{r}$ and for all $\underline{b} \in\left(\mathbb{Z} / q^{\prime \prime} \mathbb{Z}\right)^{r}$,

$$
\operatorname{gcd}\left(q^{\prime}, \underline{a}\right)=1 \text { and } \operatorname{gcd}\left(q^{\prime \prime}, \underline{b}\right)=1 \quad \Longleftrightarrow \quad \operatorname{gcd}\left(q^{\prime} q^{\prime \prime}, q^{\prime} b_{1}+q^{\prime \prime} a_{1}^{\prime}, \ldots, q^{\prime} b_{r}+q^{\prime \prime} a_{r}\right)=1
$$

The proof of the Lemma now follows from the multiplicativity of $\mu$ and of $J_{r}$.
From the above statement we deduce the following:

Corollary 3.5. Let $p$ be an odd prime, let $m \in \mathbb{N}$ be a divisor of $p-1$. If $\underline{\chi}=\left(\chi_{1}, \ldots, \chi_{r}\right)$ is a $r$-tuple of Dirichlet characters modulo $p$ and we set

$$
c_{m}(\underline{\chi}):=\frac{1}{(p-1)^{r}} \sum_{\substack{\alpha \in\left(\mathbb{F}_{p}^{*}\right)^{r} \\\left[\mathbb{F}_{p}^{*}:(\underline{\alpha}\rangle_{p}\right]=m}} \underline{\chi}(\underline{\alpha}) .
$$

Then,

$$
\begin{equation*}
c_{m}(\underline{\chi})=\frac{1}{(p-1)^{r}} \mu\left(\frac{p-1}{m \operatorname{gcd}\left(\frac{p-1}{m}, \frac{p-1}{\operatorname{ord}\left(\chi_{1}\right)}, \ldots, \frac{p-1}{\operatorname{ord}\left(\chi_{r}\right)}\right)}\right) \frac{J_{r}\left(\frac{p-1}{m}\right)}{J_{r}\left(\frac{p-1}{m \operatorname{gcd}\left(\frac{p-1}{m}, \frac{p-1}{\operatorname{ord}\left(\chi_{1}\right)}, \ldots, \frac{p-1}{\operatorname{ord}\left(\chi_{r}\right)}\right)}\right)} . \tag{3.3}
\end{equation*}
$$

Proof of Corollary 3.5. Let us fix a primitive root $g \in \mathbb{F}_{p}^{*}$. For each $j=1, \ldots, r$, let $n_{j} \in \mathbb{Z} /(p-1) \mathbb{Z}$ be such that

$$
\chi_{j}=\chi_{j}(g)=e^{\frac{2 \pi i n_{j}}{p-1}}
$$

if we write $\alpha_{j}=g^{a_{j}}$ for $j=1, \ldots, r$, then

$$
\left[\mathbb{F}_{p}^{*}:\langle\underline{\alpha}\rangle_{p}\right]=m \quad \Longleftrightarrow \quad(p-1, \underline{a})=m
$$

Therefore, naming $t=\frac{p-1}{m}$, we have

$$
\begin{align*}
c_{m}(\underline{\chi}) & =\frac{1}{(p-1)^{r}} \sum_{\substack{\underline{a} \in\left(\mathbb{F}_{p}^{*}\right)^{r} \\
(p-1, \underline{a})=m}} \chi_{1}(g)^{a_{1}} \cdots \chi_{r}(g)^{a_{r}} \\
& =\frac{1}{(p-1)^{r}} \sum_{\substack{a^{\prime} \in(\mathbb{Z} / t \mathbb{Z})^{r} \\
\left(t, \underline{a}^{\prime}\right)=1}} e^{2 \pi i \underline{a}^{\prime} \cdot \underline{n} / t} \\
& =\frac{1}{(p-1)^{r}} c_{\frac{p-1}{m}}(\underline{n}) . \tag{3.4}
\end{align*}
$$

By definition we have that ord $\left(\chi_{j}\right)=(p-1) / \operatorname{gcd}\left(n_{j}, p-1\right)$, so

$$
\frac{p-1}{m \operatorname{gcd}\left(\frac{p-1}{m}, \underline{n}\right)}=\frac{p-1}{m \operatorname{gcd}\left(\frac{p-1}{m}, \frac{p-1}{\operatorname{ord}\left(\chi_{1}\right)}, \ldots, \frac{p-1}{\operatorname{ord}\left(\chi_{r}\right)}\right)}
$$

and this concludes the proof.
For a fixed rank $r$, define $R_{p}(m):=\#\left\{\underline{a} \in(\mathbb{Z} /(p-1) \mathbb{Z})^{r}:(\underline{a}, p-1)=m\right\}$. Then using well-known properties of the Möbius function, we can write

$$
R_{p}(m)=\sum_{\underline{a} \in(\mathbb{Z} /(p-1) \mathbb{Z})^{r}} \sum_{n \left\lvert\, \frac{a_{1}}{m}\right.} \mu(n)=\sum_{n \left\lvert\, \frac{p-1}{m}\right.} \mu(n)\left[h_{m}(n)\right]^{r}
$$

where

$$
h_{m}(n)=\#\{a \in \mathbb{Z} /(p-1) \mathbb{Z}: n \mid(a / m)\}=\frac{p-1}{n m}
$$

so that

$$
R_{p}(m)=\frac{(p-1)^{r}}{m^{r}} \sum_{n \left\lvert\, \frac{p-1}{m}\right.} \frac{\mu(n)}{n^{r}}=J_{r}\left(\frac{p-1}{m}\right)
$$

Defining

$$
\begin{equation*}
S_{m}(x):=\frac{1}{m^{r}} \sum_{\substack{p \leq x \\ p \equiv 1}} \sum_{\substack{n \left\lvert\, \frac{p-1}{m}\right.}} \frac{\mu(n)}{n^{r}}=\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} \frac{1}{(p-1)^{r}} J_{r}\left(\frac{p-1}{m}\right) \tag{3.5}
\end{equation*}
$$

we have the following Lemma.

Lemma 3.6. If $m \leq(\log x)^{D}$ with $D$ arbitrary positive constant, then

$$
S_{m}(x)=C_{r, m} \operatorname{Li}(x)+O\left(\frac{x}{m^{r}(\log x)^{M}}\right)
$$

where $M$ is an arbitrary constant greater than 1 and $C_{r, m}=\sum_{n \geq 1} \frac{\mu(n)}{(n m)^{r} \varphi(n m)}$.

Proof. We choose an arbitrary positive constant $B$ and for every co-prime integers $a$ and $b$, we denote $\pi(x ; a, b)=\#\{p \leq x: p \equiv a(\bmod b)\}$, then

$$
\begin{aligned}
S_{m}(x) & =\sum_{n \leq x} \frac{\mu(n)}{(n m)^{r}} \pi(x ; 1, n m) \\
& =\sum_{n \leq(\log x)^{B}} \frac{\mu(n)}{(n m)^{r}} \pi(x ; 1, n m)+O\left(\sum_{(\log x)^{B}<n \leq x} \frac{1}{(n m)^{r}} \pi(x ; 1, n m)\right)
\end{aligned}
$$

The sum in the error term is

$$
\begin{aligned}
\sum_{(\log x)^{B}<n \leq x} \frac{1}{(n m)^{r}} \pi(x ; 1, n m) & \leq \frac{1}{m^{r}} \sum_{n>(\log x)^{B}} \frac{1}{n^{r}} \sum_{\substack{2 \leq a \leq x \\
a \equiv 1(\bmod n m)}} 1 \\
& \leq \frac{1}{m^{r+1}} \sum_{n>(\log x)^{B}} \frac{x}{n^{r+1}} \ll \frac{x}{m^{r+1}(\log x)^{r B}}
\end{aligned}
$$

For the main term we apply the Siegel-Walfisz Theorem [27], which states that for every arbitrary
positive constants $B$ and $C$, if $a \leq(\log x)^{B}$, then

$$
\pi(x ; 1, a)=\frac{\operatorname{Li}(x)}{\varphi(a)}+O\left(\frac{x}{(\log x)^{C}}\right) .
$$

So, if we restrict $m \leq(\log x)^{D}$ for any positive constant $D$;

$$
\begin{aligned}
S_{m}(x)= & \sum_{n \leq(\log x)^{B}} \frac{\mu(n)}{(n m)^{r} \varphi(m n)} \operatorname{Li}(x)+O\left(\frac{x}{(\log x)^{C}} \sum_{n \leq(\log x)^{B}} \frac{1}{(n m)^{r}}\right)+O\left(\frac{x}{m^{r+1}(\log x)^{r B}}\right) \\
= & C_{r, m} \operatorname{Li}(x)+O\left(\sum_{n>(\log x)^{B}} \frac{1}{(n m)^{r} \varphi(n m)} \operatorname{Li}(x)\right)+O\left(\frac{x \log \log x}{m^{r}(\log x)^{C}}\right) \\
& +O\left(\frac{x}{m^{r+1}(\log x)^{r B}}\right) \\
= & C_{r, m} \operatorname{Li}(x)+O\left(\frac{1}{m^{r} \varphi(m)} \sum_{n>(\log x)} \frac{1}{n^{r} \varphi(n)} \operatorname{Li}(x)\right)+O\left(\frac{x \log \log x}{m^{r}(\log x)^{C}}\right) \\
& +O\left(\frac{x}{m^{r+1}(\log x)^{r^{B}}}\right)
\end{aligned}
$$

where we have used the elementary inequality $\varphi(m n) \geq \varphi(m) \varphi(n)$. By Mertens' formula

$$
\frac{n}{\varphi(n)}=\prod_{p \mid n}\left(1-\frac{1}{p}\right)^{-1} \leq \prod_{p \leq n}\left(1-\frac{1}{p}\right)^{-1} \ll \log n
$$

then

$$
\sum_{n>(\log x)^{B}} \frac{1}{n^{r} \varphi(n)} \ll \sum_{n>(\log x)^{B}} \frac{\log n}{n^{r+1}} \ll \frac{\log \log x}{(\log x)^{r B}} .
$$

Thus

$$
\frac{1}{m^{r} \varphi(m)} \sum_{n>(\log x)^{B}} \frac{1}{n^{r} \varphi(n)} \operatorname{Li}(x) \ll \frac{1}{m^{r} \varphi(m)} \frac{x}{(\log x)^{r B}},
$$

proves the lemma for a suitable choice of $D, B$ and $C$.

Lemma 3.7. Let $\tau$ be the divisor function and $m \in \mathbb{N}$. For $x$ sufficiently large, $x>m$, we have the following inequality:

$$
\sum_{\substack{p \leq x \\ p \equiv 1(\text { mod } m)}} \tau\left(\frac{p-1}{m}\right) \leq \frac{2 x}{m} .
$$

Proof. Let us write $p-1=m k j$ so that $k j \leq(x-1) / m$ and let us set $Q=\sqrt{\frac{x-1}{m}}$ and distinguish the three cases

- $j \leq Q, k>Q$,
- $j>Q, k \leq Q$,
- $j \leq Q, k \leq Q$.

So we have the identity:

$$
\begin{aligned}
\sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \tau\left(\frac{p-1}{m}\right) & =\sum_{j \leq Q} \sum_{\substack{Q<k \leq Q^{2} \\
j \\
m j k+1 \text { prime }}} 1+\sum_{k \leq Q} \sum_{\substack{Q<j \leq \frac{Q^{2}}{k} \\
m j k+1 \text { prime }}} 1+\sum_{j \leq Q} \sum_{\substack{k \leq Q \\
m j k+1 \\
m \text { prime }}} 1 \\
& =2 \sum_{k \leq Q} \sum_{\substack{m k Q+1<p \leq x \\
p \equiv(\bmod k) m}} 1+\sum_{k \leq Q} \sum_{\substack{p \leq m k Q+1 \\
p \equiv 1(\bmod k) m}} 1 \\
& =2 \sum_{k \leq Q}(\pi(x ; 1, k m)-\pi(m k Q+1 ; 1, k m))+\sum_{k \leq Q} \pi(m k Q+1 ; 1, k m) \\
& =2 \sum_{k \leq Q} \pi(x ; 1, k m)-\sum_{k \leq Q} \pi(m k Q+1 ; 1, k m) .
\end{aligned}
$$

Using the Montgomery-Vaughan [15] version of the Brun-Titchmarsh Theorem:

$$
\pi(x ; a, q) \leq \frac{2 x}{\varphi(q) \log (x / q)}
$$

for $m \leq(\log x)^{D}$ with $D$ arbitrary positive constant, then we obtain

$$
\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} \tau\left(\frac{p-1}{m}\right) \leq 2 \sum_{k \leq Q} \frac{2 x}{\varphi(k m) \log (x / k m)} \leq \frac{2 x}{\log (x / m)} \sum_{k \leq Q} \frac{1}{\varphi(k m)} .
$$

Now substitute the elementary inequality $\varphi(k m) \geq m \varphi(k)$ and use the result of Montgomery [15]

$$
\sum_{k \leq Q} \frac{1}{\varphi(k)}=A \log Q+B+O\left(\frac{\log Q}{Q}\right)
$$

where

$$
A=\frac{\zeta(2) \zeta(3)}{\zeta(6)}=1.94360 \cdots \quad \text { and } \quad B=A \gamma-\sum_{n=1}^{\infty} \frac{\mu^{2}(n) \log n}{n \varphi(n)}=-0.06056 \ldots,
$$

which in particular implies that for $Q$ large enough

$$
A \log Q-1 \leq \sum_{k \leq Q} \frac{1}{\varphi(k)} \leq A \log Q \leq \log (x / m) .
$$

Finally

$$
\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} \tau\left(\frac{p-1}{m}\right) \leq \frac{2 x}{m} .
$$

Lemma 3.8. Let $p$ be an odd prime number and let

$$
d_{m}(\chi)=\sum_{\substack{\chi \in\left(\widehat{\mathbb{F}_{\widehat{x}}^{*}}\right)^{r} \\ \chi_{1}=\chi \neq \chi_{0}}}\left|c_{m}(\underline{\chi})\right| ;
$$

then

$$
d_{m}(\chi) \leq \frac{1}{m} \prod_{\ell \left\lvert\, \frac{p-1}{m}\right.}\left(1+\frac{1}{\ell}\right)
$$

Proof. From equation (3.4), we have

$$
d_{m}(\chi)=\frac{1}{(p-1)^{r}} \sum_{\substack{\underline{n} \in\left(\frac{\mathbb{Z}}{\left(\frac{p-1) \mathbb{Z}}{}\right)^{n} \neq 0}\right.}} \mu^{2}\left(\frac{(p-1) / m}{\left(\frac{p-1}{m}, \underline{n}\right)}\right) \frac{J_{r}\left(\frac{p-1}{m}\right)}{J_{r}\left(\frac{(p-1) / m}{\left(\frac{p-1}{m}, \underline{n}\right)}\right)}
$$

thus naming $t=\frac{p-1}{m}$ and $u=\operatorname{gcd}\left(t, n_{1}\right)$ we get

$$
d_{m}(\chi)=\frac{1}{(p-1)^{r}} \sum_{d \mid t} \mu^{2}\left(\frac{t}{d}\right) \frac{J_{r}(t)}{J_{r}\left(\frac{t}{d}\right)} H(d)
$$

where

$$
H(d):=\#\left\{\underline{x} \in\left(\frac{\mathbb{Z}}{(p-1) \mathbb{Z}}\right)^{r-1}:(u, \underline{x})=d\right\}=\left(\frac{p-1}{d}\right)^{r-1} \sum_{k \left\lvert\, \frac{u}{d}\right.} \frac{\mu(k)}{k^{r-1}}
$$

Denoting $\alpha=v_{\ell}(t)$, then

$$
\begin{aligned}
d_{m}(\chi) & =\frac{1}{(p-1)} \sum_{d \mid t} \mu^{2}\left(\frac{t}{d}\right) \frac{J_{r}(t)}{d^{r-1} J_{r}\left(\frac{t}{d}\right)} \sum_{k \left\lvert\, \frac{u}{d}\right.} \frac{\mu(k)}{k^{r-1}} \\
& \leq \frac{1}{p-1} \sum_{d \mid t} \mu^{2}\left(\frac{t}{d}\right) d=\frac{t}{p-1} \sum_{k \mid t} \frac{\mu^{2}(k)}{k} \\
& =\frac{1}{m} \prod_{\ell \mid t}\left(1+\frac{1}{l}\right)
\end{aligned}
$$

### 3.3 Proof of Theorem 1.8

Proof. We will follow the method of Stephens [24]. By exchanging the order of summation we obtain that

$$
\sum_{\substack{a \in \mathbb{Z}^{r} \\ 0<a_{1} \leq T_{1}}} N_{\langle\underline{a}\rangle, m}(x)=\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} M_{p}^{m}(\underline{T})
$$

where $M_{p}^{m}(\underline{T})$ is the number of $r$-tuples $\underline{a} \in \mathbb{Z}^{r}$, with $0<a_{i} \leq T_{i}$ and $v_{p}\left(a_{i}\right)=0$ for each $i=1, \ldots, r$, whose reductions modulo $p$ satisfies $\left[\mathbb{F}_{p}^{*}:\langle\underline{a}\rangle_{p}\right]=m$. We can write

$$
M_{p}^{m}(\underline{T})=\sum_{\substack{a \in \mathbb{Z}^{r} \\ 0<T_{1} \\ \vdots \\ 0<a_{r} \leq T_{r}}} t_{p, m}(\underline{a})
$$

where

$$
t_{p, m}(\underline{a})= \begin{cases}1 & \text { if }\left[\mathbb{F}_{p}^{*}:\langle\underline{a}\rangle_{p}\right]=m \\ 0 & \text { otherwise }\end{cases}
$$

It is easy to show that, given a $r$-tuple $\underline{\chi}$ of characters $\bmod p$, then

$$
\begin{equation*}
t_{p, m}(\underline{a})=\sum_{\underline{\chi} \in\left(\widehat{\mathbb{F}_{*}^{*}}\right)^{r}} c_{m}(\underline{\chi}) \underline{\chi}(\underline{a}) ; \tag{3.6}
\end{equation*}
$$

so we have

$$
\sum_{\substack{a \in \mathbb{Z}^{r} \\ 0<a_{1} \leq T_{1}}} N_{\langle\underline{a}\rangle, m}(x)=\sum_{\substack{p \leq x \\ \vdots \equiv 1 \\ \vdots \\ 0<a_{r} \leq T_{r}}} \sum_{\substack{a \in \mathbb{Z}^{r} \\ 0<\operatorname{Z}_{1} \leq T_{1}\\}} \sum_{\chi \in\left(\widehat{\mathbb{F}_{p}^{*}}\right) r} c_{m}(\underline{\chi}) \underline{\chi}(\underline{a}) .
$$

Let $\underline{\chi}_{0}=\left(\chi_{0}, \ldots, \chi_{0}\right)$ be the $r$-tuple consisting of all principal characters, then

$$
\begin{aligned}
c_{m}\left(\underline{\chi}_{0}\right)=\frac{1}{(p-1)^{r}} \sum_{\substack{\underline{a} \in\left(\mathbb{F}_{p}^{*}\right)^{r} \\
\left[\mathbb{F}_{p}^{*}:(\underline{a}\rangle_{p}\right]=m}} \underline{\chi}_{0}(\underline{a}) & =\frac{1}{(p-1)^{r}} \#\left\{\underline{a} \in(\mathbb{Z} /(p-1) \mathbb{Z})^{r}:(\underline{a}, p-1)=m\right\} \\
& =\frac{1}{(p-1)^{r}} R_{p}(m) .
\end{aligned}
$$

Denoting $|\underline{T}|:=\prod_{i=1}^{r} T_{i}$ and using (3.5), we can write the main term as

$$
\begin{aligned}
\frac{1}{|\underline{T}|} \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1}}} c_{m}\left(\underline{\chi}_{0}\right) \underline{\chi}_{0}(\underline{a}) & =\frac{1}{|\underline{T}|} \sum_{\substack{p \leq x \\
0<a_{r} \leq T_{r}(\bmod m)}} c_{m}\left(\underline{\chi}_{0}\right) \prod_{i=1}^{r}\left\{\left\lfloor T_{i}\right\rfloor-\left\lfloor T_{i} / p\right\rfloor\right\} \\
& =\sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} c_{m}\left(\underline{\chi}_{0}\right)\left(1-\frac{r}{p}+\cdots+\frac{1}{p^{r}}+\sum_{i=1}^{r} O\left(\frac{1}{T_{i}}\right)\right) \\
& =\sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} c_{m}\left(\underline{\chi}_{0}\right)+O\left(\sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \frac{1}{p}\right)+O\left(\frac{x}{T^{*} \log x}\right) \\
& =S_{m}(x)+O(\log \log x)+O\left(\frac{x}{T^{*} \log x}\right) .
\end{aligned}
$$

Since $m \leq(\log x)^{D}, D>0$, and $T^{*}>\exp \left(4(\log x \log \log x)^{1 / 2}\right)$, we can apply Lemma 3.6:

$$
\frac{1}{|\underline{T}|} \sum_{\substack{p \leq x \\ p \equiv 1(\bmod \operatorname{mon} \\ m}} \sum_{\substack{\underline{a} \in \mathbb{Z}_{1}^{r} \leq T_{1} \\ 0<a_{1} \\ 0<a_{r} \leq T_{r}}} c_{m}\left(\underline{\chi}_{0}\right) \underline{\chi}_{0}(\underline{a})=C_{r, m} \operatorname{Li}(x)+O\left(\frac{x}{m^{r}(\log x)^{M}}\right)
$$

where $M>1$.

For the error term we need to estimate the sum;

$$
\begin{aligned}
E_{r, m}(x) & :=\frac{1}{|\underline{T}|} \sum_{\substack{p \leq x \\
p \equiv 1 \\
(\bmod m)}} \sum_{\substack{\widehat{\chi}\left(\widehat{\mathbb{F}_{p}^{*}}\right)^{r} \backslash\left\{\underline{\chi}_{0}\right\}}}\left|c_{m}(\underline{\chi}) \sum_{\substack{a \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1} \\
\vdots \\
0<a_{r} \leq T_{r}}} \underline{\chi}(\underline{a})\right| \\
& \ll \sum_{i=1}^{r} \frac{1}{T_{i}} \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \sum_{\widehat{\chi} \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}\right\}} d_{m}\left(\chi_{i}\right)\left|\sum_{\substack{a \in \mathbb{Z} \\
0<a \leq T_{i}}} \chi_{i}(a)\right|
\end{aligned}
$$

where

$$
d_{m}(\chi)=\sum_{\substack{\chi \in\left(\widehat{\mathbb{F}_{p}^{*}}\right)^{r} \\ \chi_{1}=\chi \neq \chi_{0}}}\left|c_{m}(\underline{\chi})\right| .
$$

Define

$$
\begin{equation*}
E_{r, m}^{j}(x):=\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} \sum_{\chi_{i} \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}\right\}} d_{m}\left(\chi_{i}\right)\left|\sum_{\substack{a \in \mathbb{Z} \\ 0<a \leq T_{i}}} \chi_{i}(a)\right| \tag{3.7}
\end{equation*}
$$

then using Holder's inequality

$$
\begin{align*}
\left\{E_{r, m}^{j}(x)\right\}^{2 s_{i}} & \leq\left\{\sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \sum_{\chi_{i} \in \widehat{\mathbb{F}_{p}^{*} \backslash\left\{\chi_{0}\right\}}}\left\{d_{m}\left(\chi_{i}\right)\right\}^{\frac{2 s_{i}}{2 s_{i}-1}}\right\}^{2 s_{i}-1} \\
& \times \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \sum_{\substack{\chi_{i} \in \widehat{\left.\mathbb{F}_{\mathcal{F}}\right\rangle} \backslash\left\{\chi_{0}\right\}}}\left|\sum_{\substack{a \in \mathbb{Z} \\
0<a \leq T_{i}}} \chi_{i}(a)\right|^{2 s_{i}} . \tag{3.8}
\end{align*}
$$

If $g$ is a primitive root modulo $p$, then for every $j=1, \ldots, r$ we write again $\chi_{j}(g)=e^{2 \pi i n_{j} /(p-1)}$ for
a certain $n_{j} \in \mathbb{Z} /(p-1) \mathbb{Z}$, by equation (3.4) so that

$$
\sum_{\underline{\chi} \in\left(\widehat{\mathbb{F}_{p}^{*}}\right)^{r} \backslash\left\{\underline{\chi}_{0}\right\}} c_{m}(\underline{\chi})=\frac{1}{(p-1)^{r}} \sum_{\underline{n} \in\left(\frac{\mathbb{Z}}{(p-1) \mathbb{Z}}\right)^{r} \backslash\{\underline{0}\}} c_{\underline{p}-1}^{m}(\underline{n}) .
$$

Thus, using Lemma 3.4 and indicating again $t=(p-1) / m$ we have

$$
\begin{aligned}
\sum_{\chi_{i} \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}\right\}} d_{m}\left(\chi_{i}\right) & \leq \sum_{\underline{\chi} \in\left(\widehat{\mathbb{F}_{p}^{*}}\right)^{r} \backslash\left\{\underline{\chi}_{0}\right\}}\left|c_{m}(\underline{\chi})\right| \\
& \leq \sum_{d \mid t} \mu^{2}\left(\frac{t}{d}\right)\left[\frac{J_{r}(t)}{(p-1)^{r} J_{r}(t / d)}\right] \#\left\{\underline{n} \in(\mathbb{Z} /(p-1) \mathbb{Z})^{r}:(t, \underline{n})=d\right\} \\
& =\sum_{d \mid t} \mu^{2}\left(\frac{t}{d}\right)\left[\frac{J_{r}(t)}{(p-1)^{r} J_{r}(t / d)}\right]\left(\frac{p-1}{d}\right)^{r} \sum_{k \left\lvert\, \frac{t}{d}\right.} \frac{\mu(k)}{k^{r}} \\
& =\frac{J_{r}(t)}{t^{r}} \sum_{d \mid t} \mu^{2}\left(\frac{t}{d}\right)=\prod_{\ell \mid t}\left(1-\frac{1}{\ell^{r}}\right) 2^{\omega(t)} \leq 2^{\omega(t)} .
\end{aligned}
$$

Calling $D_{m}(p)=\max _{\chi \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}\right\}}\left\{d_{m}(\chi)\right\}$ and using Lemmas 3.8 and 3.7 in equation (3.8) we have

$$
\begin{aligned}
\sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \sum_{\chi \in \widehat{\mathbb{F}_{p}^{*} \backslash\{\chi 0\}}}\left\{d_{m}(\chi)\right\}^{\frac{2 s_{i}}{2 s_{i}-1}} & \leq \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \sum_{\chi \in \widehat{\mathbb{P}_{p}^{*}} \backslash\left\{\chi_{0}\right\}} d_{m}(\chi)\left\{d_{m}(\chi)\right\}^{\frac{1}{s_{i}-1}} \\
& \leq \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}}\left\{D_{m}(p)\right\}^{\frac{1}{2 s_{i}-1}} \sum_{\chi \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}\right\}} d_{m}(\chi) \\
& \leq \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}}\left\{D_{m}(p)\right\}^{\frac{1}{2 s_{i}-1}} 2^{\omega\left(\frac{p-1}{m}\right)} \\
& \leq \frac{1}{m} \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} \prod_{\substack{\left.l\right|^{p-1} \\
m}}\left(1+\frac{1}{l}\right) 2^{\omega\left(\frac{p-1}{m}\right)} \\
& \ll \frac{1}{m} \log \log x \sum_{p \equiv 1} \sum_{p \leq x} \tau\left(\frac{p-1}{m}\right) \ll \frac{1}{m^{2}} x \log \log \log x .
\end{aligned}
$$

To estimate the other term in (3.8) we use Lemma 5 in [24]:

$$
\sum_{\substack{p \leq x \\ p \equiv 1 \\(\bmod m)}} \sum_{\substack{\chi_{i} \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}\right\}}}\left|\sum_{\substack{a \in \mathbb{Z}^{r} \\ 0<a_{i} \leq T_{i}}} \chi_{i}\left(a_{i}\right)\right|^{2 s_{i}} \ll\left(x^{2}+T_{i}^{s_{i}}\right) T_{i}^{s_{i}}\left(\log \left(e T_{i}^{s_{i}-1}\right)\right)^{s_{i}{ }^{2}-1} .
$$

So, for every positive constant $M>1$, we find

$$
\frac{1}{|\underline{T}|} \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\ 0<a_{1} \leq T_{1} \\ \vdots \\ 0<a_{r} \leq T_{r}}} N_{\langle\underline{\langle }\rangle, m}(x)=C_{r, m} \operatorname{Li}(x)+O\left(\frac{x}{m^{r}(\log x)^{M}}\right)+O\left(\sum_{i=1}^{r} \frac{x}{T_{i} \log x}\right)+E_{r, m}(x)
$$

where

$$
E_{r, m}(x) \ll \sum_{i=1}^{r} \frac{1}{T_{i}}\left[\left(\frac{x \log \log x}{m^{2}}\right)^{2 s_{i}-1}\left(x^{2}+T_{i}^{s_{i}}\right) T_{i}{ }^{s_{i}}\left(\log \left(e T_{i}^{s_{i}-1}\right)\right)^{s_{i}{ }^{2}-1}\right]^{\frac{1}{2 s_{i}}} .
$$

If we choose $s_{i}=\left\lfloor\frac{2 \log x}{\log T_{i}}\right\rfloor+1$ for $i=1, \ldots, r$, then $T_{i}^{s_{i}-1} \leq x^{2}<T_{i}^{s_{i}}$ and

$$
E_{r, m}(x) \ll \frac{1}{m} \sum_{i=1}^{r}(x \log \log x)^{1-\frac{1}{2 s_{i}}}\left(\log \left(e x^{2}\right)\right)^{\frac{s_{i}{ }^{2}-1}{2 s_{i}}} .
$$

Now, if $T_{i}>x^{2}$ for all $i=1, \ldots, r$, then $s_{1}=\cdots=s_{r}=1$ and

$$
E_{r, m}(x) \ll \frac{1}{m}(x \log \log x)^{1 / 2} ;
$$

in particular, we have $E_{r, m}(x) \ll x /(\log x)^{M}$ for every $M>1$. If $T_{j} \leq x^{2}$ for some $j \in\{1, \ldots, r\}$, then $s_{j} \geq 2$ and the corresponding contribution to $E_{r, m}(x)$ will be

$$
E_{r, m}^{j}(x) \ll \frac{1}{m}(x \log \log x)^{1-\frac{1}{2 s_{j}}}\left(\log \left(e x^{2}\right)\right)^{\frac{3 \log x}{2 \log T_{j}}} .
$$

By hypothesis

$$
\begin{equation*}
T^{*}>\exp \left(4(\log x \log \log x)^{1 / 2}\right), \tag{3.9}
\end{equation*}
$$

so

$$
E_{r, m}(x) \ll \frac{1}{m} x \log \log x\left(T^{*}\right)^{-\frac{1}{16}}
$$

also in this case, using (3.9), we have $E_{r, m}(x) \ll x /(\log x)^{M}$ for every $M>1$. This proves the first statement of the Theorem.

In order to prove the second statement of the Theorem, we now consider

$$
\begin{aligned}
& H:=\frac{1}{|\underline{T}|} \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1}}}\left\{N_{\langle\underline{a}\rangle, m}(x)-C_{r, m} \operatorname{Li}(x)\right\}^{2} \\
& \leq \frac{1}{0<a_{r} \leq T_{r}} \\
&(\underline{T} \mid \\
&\left.\sum_{\substack{p, q \leq x \\
p, q \equiv 1(\bmod m)}} M_{p, q}^{m}(\underline{T})-2 C_{r, m} \operatorname{Li}(x) \sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} M_{p}^{m}(\underline{T})+|\underline{T}|\left(C_{r, m}\right)^{2} \operatorname{Li}^{2}(x)\right)
\end{aligned}
$$

where $M_{p, q}^{m}(\underline{T})$ denotes the number of $r$-tuples $\underline{a} \in \mathbb{Z}^{r}$, with $a_{i} \leq T_{i}$ and $v_{p}\left(a_{i}\right)=v_{q}\left(a_{i}\right)=0$ for each $i=1, \ldots, r$, whose reductions modulo $p$ and $q$ satisfy $\left[\mathbb{F}_{p}^{*}:\langle\underline{a}\rangle_{p}\right]=m$ and $\left[\mathbb{F}_{q}^{*}:\langle\underline{a}\rangle_{q}\right]=m$ simultaneously. Then, by applying the first result of the statement, we obtain, for every constant $M^{\prime}>2$,

$$
H \leq \frac{1}{|\underline{T}|} \sum_{\substack{p, q \leq x \\ p, q \equiv 1(\bmod m)}} M_{p, q}^{m}(\underline{T})-\left(C_{r, m}\right)^{2} \mathrm{Li}^{2}(x)+O\left(\frac{x^{2}}{(\log x)^{M^{\prime}}}\right) .
$$

If we write

$$
\sum_{\substack{p, q \leq x \\ p, q \equiv 1(\bmod m)}} M_{p, q}^{m}(\underline{T})=\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} M_{p}^{m}(\underline{T})+\sum_{\substack{p, q \leq x \\ p, q \equiv 1(\bmod m) \\ p \neq q}} M_{p, q}^{m}(\underline{T}),
$$

we can apply again the first result of the statement to get

$$
\sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}} M_{p}^{m}(\underline{T})=C_{r, m}|\underline{T}| \operatorname{Li}(x)+O\left(\frac{|\underline{T}| x}{(\log x)^{M}}\right)
$$

where $M>1$. In the same spirit as in the proof of the first part of the statement, we use (3.6).
Hence

$$
\begin{aligned}
& \sum_{\substack{p, q \leq x \\
p, q \equiv 1(\bmod m) \\
p \neq q}} M_{p, q}^{m}(\underline{T})=\sum_{\substack{p, q \leq x \\
p, q \equiv 1 \\
p \neq q}} \sum_{\substack{(\bmod ) \\
p \neq q}} \sum_{\substack{\underline{a} \in \mathbb{Z}_{1}^{r} \\
0<a_{1} \leq T_{1} \\
0 \\
0<a_{r} \leq T_{r}}} t_{p, m}(\underline{a}) t_{q, m}(\underline{a}) \\
& =\sum_{\substack{p, q \leq x \\
p, q \equiv 1 \\
p \neq q}} \sum_{\substack{\bmod }} \sum_{\substack{\underline{\chi}_{1} \in\left(\widehat{\mathbb{F}_{p}}\right)^{r} \underline{\chi}_{2} \in\left(\widehat{\mathbb{F}_{q}}\right)^{r}}} c_{m}\left(\underline{\chi}_{1}\right) c_{m}\left(\underline{\chi}_{2}\right) \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1} \\
\vdots \\
0<a_{r} \leq T_{r}}} \underline{\chi}_{1}(\underline{a}) \underline{\chi}_{2}(\underline{a}) .
\end{aligned}
$$

Therefore,

$$
\sum_{\substack{p, q \leq x \\ p, q \equiv 1(\bmod m)}} M_{p, q}^{m}(\underline{T})=H_{1}+2 H_{2}+H_{3}+O(|\underline{T}| \operatorname{Li}(x))
$$

where $H_{1}, H_{2}, H_{3}$ are the contributions to the double sum when $\underline{\chi}_{1}=\underline{\chi}_{2}=\underline{\chi}_{0}$, only one between $\underline{\chi}_{1}$ and $\underline{\chi}_{2}$ is equal to $\underline{\chi}_{0}$, neither $\underline{\chi}_{1}$ nor $\underline{\chi}_{2}$ is $\underline{\chi}_{0}$, respectively. First we deal with the inner sum in $H_{1}$. To avoid confusion, we set $\underline{\chi}_{0}^{p}$ and $\underline{\chi}_{0}^{q}$ as a $r$-tuples whose all entries are principal characters
$(\bmod p)$ and $(\bmod q)$ respectively, so that

$$
\sum_{\substack{a \in \mathbb{Z}^{r} \\ 0<a_{1} \leq T_{1} \\ \vdots \\ \vdots \\ 0<a_{r} \leq T_{r}}} \underline{\chi}_{0}^{p}(\underline{a}) \underline{\chi}_{0}^{q}(\underline{a})=\prod_{i=1}^{r}\left\{\left\lfloor T_{i}\right\rfloor-\left\lfloor\frac{T_{i}}{p}\right\rfloor-\left\lfloor\frac{T_{i}}{q}\right\rfloor+\left\lfloor\frac{T_{i}}{p q}\right\rfloor\right\} .
$$

Then, for every constant $M^{\prime}>2$, Lemma 3.6 gives

$$
\begin{aligned}
H_{1} & =\sum_{\substack{p, q \leq x \\
p, q \equiv 1(\bmod m) \\
p \neq q}} c_{m}\left(\underline{\chi}_{0}^{p}\right) c_{m}\left(\underline{\chi}_{0}^{q}\right) \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1} \\
\vdots \\
0<a_{r} \leq T_{r}}} \underline{\chi}_{0}^{p}(\underline{a}) \underline{\chi}_{0}^{q}(\underline{a}) \\
& =|\underline{T}| \sum_{\substack{p, q \leq x \\
p, q \equiv 1 \\
p \neq q}} c_{m}\left(\underline{\chi}_{0}^{p}\right) c_{m}\left(\underline{\chi}_{0}^{q}\right)\left(1-\frac{r}{p}-\frac{r}{q}+\cdots+\frac{1}{(p q)^{r}}+\sum_{i=1}^{r} O\left(\frac{1}{T_{i}}\right)\right) \\
& \left.=|\underline{T}|\left(\sum_{\substack{p \leq x \\
p \neq 1}} c_{m}\left(\underline{\chi}_{0}\right)\right)^{2}-\sum_{\substack{p \leq x \\
(\bmod m)}}\left(c_{m}\left(\underline{\chi}_{0}^{p}\right)\right)^{2}\right)\left(1+O\left(\frac{1}{T^{*}}\right)\right)+|\underline{T}| O\left(\frac{x \log \log \log x}{\log x}\right) \\
& =|\underline{T}|\left(S_{m}^{2}(x)+O\left(\frac{x^{2}}{T^{*}(\log x)^{2}}\right)+O\left(\frac{x \log \log x}{\log x}\right)\right) \\
& =|\underline{T}|\left(C_{r, m}^{2} \operatorname{Li}^{2}(x)+O\left(\frac{x^{2}}{m^{r}(\log x)^{M^{\prime}}}\right)\right) .
\end{aligned}
$$

Focusing on $H_{2}$ and supposing $\underline{\chi}_{1}=\underline{\chi}_{0} \neq \underline{\chi}_{2}$, then

$$
\begin{aligned}
& =\sum_{\substack{p \leq x \\
p \equiv 1(\bmod m)}} c_{m}\left(\underline{\chi}_{0}^{p}\right) \sum_{\substack{q \equiv 1 \\
q \equiv 1 \\
(\bmod m) \\
q \neq p}} \sum_{\substack{\underline{\chi}_{2} \in\left(\widehat{\mathbb{F}_{q}^{*}}\right)^{r} \backslash \backslash\left\{\underline{\chi}_{0}^{q}\right\}}} c_{m}\left(\underline{\chi}_{2}\right) \sum_{\substack{a \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1} \\
\vdots \\
\\
\\
0<a_{2} \leq T_{r} \\
p \nmid \prod_{i=1}^{r} a_{i}}}(\underline{a}) .
\end{aligned}
$$

The quantity

$$
U_{2}:=\sum_{q \equiv 1} \sum_{\substack{q \leq x \\(\bmod m) \underline{\chi}_{2} \in\left(\widehat{\mathbb{F}_{q}^{*}}\right)^{r} \backslash\left\{\underline{\chi}_{0}^{q}\right\}}}\left|c_{m}\left(\underline{\chi}_{2}\right) \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\ 0<a_{1} \leq T_{1} \\ \underline{\chi}_{2} \\ \vdots \\ 0<a_{r} \leq T_{r}}}\right|
$$

can be estimated as before through Holder's inequality combined with the large sieve inequality to get $U_{2} \ll x /(\log x)^{M}$ with $M>1$, while Lemma 3.7 gives the following upper bound:

$$
\begin{aligned}
V_{2} & :=\sum_{\substack{q \leq x \\
q \equiv 1(\bmod m)}} \sum_{\substack{\chi_{2} \in\left(\widehat{\mathbb{F}_{q}^{*}}\right)^{r} \backslash\left\{\underline{q}_{0}^{q}\right\}}}\left|c_{m}\left(\underline{\chi}_{2}\right) \sum_{\substack{a \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1} \\
\vdots \\
0<a_{2} \leq T_{r} \\
p \mid \prod_{i=1}^{r} a_{i}}} \underline{\chi}_{2}(\underline{a})\right| \ll \frac{|\underline{T}|}{p^{r}} \sum_{\substack{q \leq x \\
q \equiv 1(\bmod m)}} \sum_{\substack{\underline{\chi}_{2} \in\left(\widehat{\mathbb{F}_{q}^{*}}\right)^{r} \backslash\left\{\underline{\chi}_{0}^{q}\right\}}}\left|c_{m}\left(\underline{\chi}_{2}\right)\right| \\
& \ll \frac{|\underline{T}|}{p^{r}} \sum_{\substack{q \leq x \\
q \equiv 1 \\
(\bmod m)}} \tau\left(\frac{q-1}{m}\right) \ll \frac{|\underline{T}| x}{p^{r} m} .
\end{aligned}
$$

So, for every constant $M^{\prime}>2$,

$$
H_{2} \leq \sum_{\substack{p \leq x \\ p \equiv 1(\bmod m)}}\left(U_{2}+V_{2}\right) \ll \frac{|\underline{T}| x^{2}}{(\log x)^{M^{\prime}}}
$$

Finally, we notice that for $\chi_{1} \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}^{p}\right\}$ and $\chi_{2} \in \widehat{\mathbb{F}_{q}^{*}} \backslash\left\{\chi_{0}^{q}\right\}$, with $p \neq q$, then $\chi_{1} \chi_{2}$ is a primitive character modulo $p q$. Consequently, given

$$
H_{3}=\sum_{\substack{p, q \leq x \\ p, q \equiv 1 \\ p \neq q \\ p \neq q}} \sum_{\substack{\bmod )}} \sum_{\substack{\underline{\chi}_{1} \in\left(\widehat{\mathbb{F}_{p}^{*}}\right)^{r} \backslash\left\{\underline{\chi}_{0}^{p}\right\} \\ \underline{\chi}_{2} \in\left(\widehat{\left.\mathbb{F}_{q}^{*}\right)^{r} \backslash\left\{\underline{\chi}_{0}^{q}\right\}}\right.}} c_{m}\left(\underline{\chi}_{1}\right) c_{m}\left(\underline{\chi}_{2}\right) \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\ 0<a_{1} \leq T_{1}}} \underline{\chi}_{1}(\underline{a}) \underline{\chi}_{2}(\underline{a})
$$

once again we can apply Holder's inequality and the large sieve (Lemma 5 in [24]) to obtain an upper bound for $H_{3}$. First, notice that since the $r$-tuple of characters, $\underline{\chi}_{1}$ and $\underline{\chi}_{2}$, appearing in $H_{3}$ are both non-principal and indicating with $\chi_{1, i}$ the $i$-th component of the $r$-tuple $\underline{\chi}_{1}$ of Dirichlet characters of modulus $p$ (similarly for $\chi_{2, i}$ ), the estimate for $H_{3}$ comes from a diagonal part $H_{3}^{d}$ (in which for a certain $i \in\{1, \ldots, r\}$ both $\chi_{1, i}$ and $\chi_{2, i}$ are non-principal) plus a non-diagonal part $H_{3}^{n d}$ (in which for none of the indices $i \in\{1, \ldots, r\}$ is possible to have $\chi_{1, i}$ and $\chi_{2, i}$ both non-principal): explicitly, $H_{3}^{d}=\sum_{i=1}^{r} H_{3, i}$, where

$$
\begin{aligned}
& H_{3, i}:=\sum_{\substack{p, q \leq x \\
p, q \equiv 1 \\
p \neq q \\
p \neq q}} \sum_{\substack{\text { mod } \\
\chi_{1} \in\left(\widehat{\mathbb{F}_{p}^{*}}\right)^{\prime} \backslash\left\{\chi_{0}^{p}\right\}}} \sum_{\substack{\chi_{2} \in\left(\widehat{\mathbb{F}_{q}^{*}}\right)^{r} \backslash\left\{\underline{\chi}_{0}^{q}\right\}}} c_{m}\left(\underline{\chi}_{1}\right) c_{m}\left(\underline{\chi}_{2}\right) \sum_{\substack{\underline{a} \in \mathbb{Z}^{r} \\
0<a_{1} \leq T_{1}}} \underline{\chi}_{1}(\underline{a}) \underline{\chi}_{2}(\underline{a}) \\
& \leq \frac{|\underline{T}|}{T_{i}} \sum_{\substack { p, q \leq x \\
p, q \equiv 1 \\
\begin{subarray}{c}{q \leq \bmod m)^{p \neq q} \\
p \neq q{ p , q \leq x \\
p , q \equiv 1 \\
\begin{subarray} { c } { q \leq \operatorname { m o d } m ) ^ { p \neq q } \\
p \neq q } }\end{subarray}} \sum_{\widehat{\chi_{1, i}} \in} \sum_{\widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}^{p}\right\}} d_{m}\left(\chi_{1, i}\right) d_{m}\left(\chi_{2, i}\right)\left|\sum_{0<a_{i} \leq T_{i}} \chi_{1, i}\left(a_{i}\right) \chi_{2, i}\left(a_{i}\right)\right|,
\end{aligned}
$$

while for $H_{3}^{\text {nd }}=\sum_{\substack{i, j=1 \\ i \neq j}}^{r} H_{3, i j}$, with

$$
\begin{aligned}
& \leq \frac{|\underline{T}|}{T_{i} T_{j}} \sum_{\substack{p, q \leq x \\
p, q \equiv 1 \\
p \neq q}} \sum_{\substack{\text { mod }}} \sum_{\substack{\chi_{1, i} \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}^{p}\right\}}} d_{\chi_{2, j} \in \widehat{\mathbb{F}_{q}^{*}} \backslash\left\{\chi_{0}^{q}\right\}}\left(\chi_{1, i}\right) d_{m}\left(\chi_{2, j}\right)\left|\sum_{\substack{0<a_{i} \leq T_{i} \\
0<a_{j} \leq T_{j}}} \chi_{1, i}\left(a_{i}\right) \chi_{2, j}\left(a_{j}\right)\right| .
\end{aligned}
$$

Dealing first with $H_{3, i}$, we use again Holder's inequality together with the large sieve to get

$$
\begin{aligned}
& \frac{H_{3, i}}{|\underline{T}|} \ll \frac{1}{T_{i}}\left\{\sum_{\substack{p, q \leq x \\
p, q \equiv 1 \\
p \neq q}} \sum_{\substack{\text { mod } m) \\
\chi_{1, i} \in \widehat{\overparen{F}}^{*} \backslash\left\{\chi_{0}^{p}\right\} \\
\chi 2, i \in \mathbb{F}_{q}^{*} \backslash\left\{\chi_{0}^{q}\right\}}}\left[d_{m}\left(\chi_{1, i}\right) d_{m}\left(\chi_{2, i}\right)\right]^{\frac{2 s_{i}}{2 s_{i}-1}}\right\}^{\frac{2 s_{i}-1}{2 s_{i}}} \\
& \times\left\{\sum_{\substack { p, q \leq x \\
p, q=1 \\
\begin{subarray}{c}{(\bmod m) \\
p \neq q{ p , q \leq x \\
p , q = 1 \\
\begin{subarray} { c } { ( \operatorname { m o d } m ) \\
p \neq q } }\end{subarray}} \sum_{(\bmod p q)}\left|\sum_{0<a_{i} \leq T_{i}} \eta\left(a_{i}\right)\right|^{2 s_{i}}\right\}^{\frac{1}{2 s_{i}}} \\
& \ll \frac{1}{T_{i}}\left\{\left(\frac{x \log \log x}{m^{2}}\right)^{4 s_{i}-2}\left(x^{4}+T_{i}^{s_{i}}\right) T_{i}^{s_{i}}\left(\log \left(e T_{i}^{s_{i}-1}\right)\right)^{s_{i}^{2}-1}\right\}^{\frac{1}{2 s_{i}}} .
\end{aligned}
$$

We now choose $s_{i}=\left\lfloor\frac{4 \log x}{\log T_{i}}\right\rfloor+1$, so that $T_{i}^{s_{i}-1} \leq x^{4} \leq T_{i}^{s_{i}}$ and

$$
\frac{H_{3, i}}{|\underline{T}|} \ll \frac{1}{m^{2}} x^{2-\frac{1}{s_{i}}}(\log \log x)^{2}\left(\log \left(e x^{4}\right)\right)^{\frac{s_{i}^{2}-1}{2 s_{i}}} .
$$

Now, if $T_{i}>x^{4}$ then $s_{i}=1$ and $H_{3, i} /|\underline{T}| \ll x(\log \log x)^{2}$. Otherwise, if $T_{i} \leq x^{4}$ then $s_{i} \geq 2$ and, if $T_{i}>\exp \left(6(\log x \log \log x)^{1 / 2}\right)$, similar to what was done to prove the first statement of the

Theorem, we get

$$
\frac{H_{3, i}}{|\underline{T}|} \ll x^{2-\frac{1}{s_{i}}}(\log \log x)^{2}\left(\log \left(e x^{4}\right)\right)^{\frac{3 \log x}{\log T_{i}}} \ll \frac{x^{2}}{(\log x)^{D}}
$$

for any positive constant $D>2$.
It remains to estimate $H_{3, i j}$, with $i \neq j$ : it can be factorized in two products, and after using same methods in (3.7), we have

$$
\begin{aligned}
& \frac{H_{3, i j}}{|\underline{T}|} \ll \frac{1}{T_{i} T_{j}} \sum_{\substack{p \leq x \\
(\bmod m)^{2}}} \sum_{\chi_{1, i} \in \widehat{\mathbb{F}_{p}^{*}} \backslash\left\{\chi_{0}^{p}\right\}} d_{m}\left(\chi_{1, i}\right)\left|\sum_{0<a_{i} \leq T_{i}} \chi_{1, i}\left(a_{i}\right)\right| \\
& \times \sum_{q \equiv 1} \sum_{q \leq x} d_{m}\left(\chi_{2, j}\right)\left|\sum_{0<a_{j} \leq T_{j}} \chi_{2, j}\left(a_{j}\right)\right| \\
& \ll \frac{1}{T_{i}}\left\{\left(\frac{x \log \log x}{m^{2}}\right)^{2 s_{i}-1}\left(x^{2}+T_{i}^{s_{i}}\right) T_{i}^{s_{i}}\left(\log \left(e T_{i}^{s_{i}-1}\right)\right)^{s_{i}^{2}-1}\right\}^{\frac{1}{2 s_{i}}} \\
& \times \frac{1}{T_{j}}\left\{\left(\frac{x \log \log x}{m^{2}}\right)^{2 s_{j}-1}\left(x^{2}+T_{j}^{s_{j}}\right) T_{j}^{s_{j}}\left(\log \left(e T_{j}^{s_{j}-1}\right)\right)^{s_{j}^{2}-1}\right\}^{\frac{1}{2 s_{j}}}
\end{aligned}
$$

Similar to what was done to estimate the error term (3.7), we choose $s_{i}=\left\lfloor\frac{2 \log x}{\log T_{i}}\right\rfloor+1$ and $s_{j}=\left\lfloor\frac{2 \log x}{\log T_{j}}\right\rfloor+1$, so that

$$
\frac{H_{3, i j}}{|\underline{T}|} \ll \frac{x^{2}}{(\log x)^{E}}
$$

for every constant $E>2$.
Eventually, since $H_{3} \leq H_{3}^{d}+H_{3}^{\text {nd }}$, summing the upper bounds for $H_{1}, H_{2}$ and $H_{3}$ we get the proof of second part of the Theorem 1.4.

Corollary 3.9. For any $\epsilon>0$, let

$$
\mathcal{H}:=\left\{\underline{a} \in \mathbb{Z}^{r}: 0<a_{i} \leq T_{i}, i \in\{1, \ldots, r\},\left|N_{\underline{a}, m}(x)-C_{r, m} \operatorname{Li}(x)\right|>\epsilon \operatorname{Li}(x)\right\} ;
$$

then, supposing $T_{i}>\exp \left(6(\log x \log \log x)^{1 / 2}\right)$ for every $i=1, \ldots, r$, we have

$$
\# \mathcal{H} \leq K|\underline{T}| / \epsilon^{2}(\log x)^{F}
$$

for every positive constant $F$.

Proof. See [24] (Corollary, page 187).

## Chapter 4

## Codes

In this chapter, we include some sample codes that were used to generate the tables in this thesis, they were written in Pari.

The first code we include generates the data for $A_{\Gamma_{r}}$, where $\Gamma_{r}=\left\langle 2, \ldots, p_{r}\right\rangle$ is the group generated by the first $r$ primes. The results are given in the first row of Table 2.2.

```
{P=2+3+5+7+11+13+17;
A=vector(7);
A[1]=znorder (Mod}(2,3))+znorder (Mod (2,5))+znorder (Mod (2,7))+znorder (Mod (2,11))
+znorder (Mod(2,13))+znorder (Mod (2,17));
A[2]=lcm(znorder (Mod (2,5)), znorder (Mod (3,5)))+lcm(znorder (Mod (2,7)),
znorder(Mod(3,7)))+lcm(znorder(Mod}(2,11)),\operatorname{znorder}(\operatorname{Mod}(3,11))
+lcm(znorder(Mod}(2,13)),znorder(Mod(3,13))
+lcm(znorder (Mod (2,17)),znorder (Mod (3,17)));
A[3]=lcm(lcm(znorder (Mod (2,7)),znorder (Mod (3,7))),\operatorname{znorder (Mod (5,7)))}
+lcm(lcm(znorder (Mod}(2,11)),znorder(Mod(3,11))),znorder(Mod(5,11)))
```

```
+lcm(lcm(znorder (Mod}(2,13)),znorder(Mod (3,13))),znorder(Mod (5,13)))
+lcm(lcm(znorder(Mod(2,17)),znorder(Mod(3,17))),znorder(Mod (5,17)));

);print(A*1./P)}
```

The second code below generates the data for $C_{\Gamma_{r}}$, where $\Gamma_{r}=\left\langle 2, \ldots, p_{r}\right\rangle$ is the group generated by the first $r$ primes which were given in the first row of Table 2.2.

```
\read(cohen)
K(j,r)=j/(j+1-j^(r+2));
kk(ee,r)=RIS=1;fordiv(ee,X,if(isprime(X),RIS=RIS*K(X,r)));RIS;
{
for(r=1,7,U=1;P=round(prodeuler(Z=2,prime(r),Z));
fordiv(P,T,if(T>1,U=U+kk(2*T,r)/2^((r+2)*max(0,valuation(quaddisc(T)/2,2)))));
print(U*prodeulerrat(1-x/(x^(r+2)-1))))
}
```
